The President said, that as Mr. Burke had stated, what had been read was not a regularly prepared paper, but a letter written to Mr. Burke regarding this system of construction. The system was the outcome of special requirements in American cities, and could not well be compared with work done in Canada or the old country. The growth of American cities rendered necessary the erection of these enormously high buildings, and as a result this steel construction with curtain walls had been developed in New York and Chicago; especially the latter, where, despite its great area, the business centre was somewhat congested. When the development began, it was soon found more economical to run up 13, 14 or 20 storeys. A building which consisted of seven or eight storeys was built, which was found not to pay as large interest as it ought, and it was taken down and replaced by one ten or twelve storeys in height. The first building was a steel construction, with nothing more or less than a 4½ inch casing of pressed brick outside, and a curtain wall of some other brick inside. He remembered seeing those bricks being fastened at intervals with copper wire to upright angle irons, to stay this wall. With regard to the question of temperature affecting iron or steel construction, he did not think that entered into consideration at all, because, in a building the iron work is subject to practically the same temperature all the year round, and there is very little of it exposed to the extremes of heat and cold, as it is nearly all covered. In regard to shrinkage, between the two systems there must be some shrinkage, but it was reduced very considerably by the use of cement instead of the ordinary mortar. He understood there was a shrinkage of ⅝ inch in twelve feet of first-class brick wall; after the building had been up and settled to a limited extent there would be that skrinkage in the course of time. Of course that was considerable, but he was inclined to attribute it entirely to the use of ordinary mortar, and believed where the brick was laid in cement there was practically very little shrinkage. It was evident that whatever shrinkage there was must accommodate itself in some way or other, because the important fact remained that the buildings had not developed any serious defects; and theorizing was of little benefit so long as the practical outcome showed the plan of construction to be serviceable. There had been a great deal of discussion in papers devoted to such matters on this subject, but he could not tell just where to lay his hand on the information at present. The architectural appearance of a building, of course, was another question, but that, as a rule, was not considered in this class of buildings to any great extent; they were required for a certain purpose, and it was incumbent upon the architect to do the best he could under limitations. After all, the buildings were to all intents and purposes, in a sense, the works of engineers rather than architects.

FRENCH DECORATIVE ART.

By W. H. Elliott.

It is interesting to study the different periods of French art in connection with, and as they reflect the scenes and characters intimately associated with them. One might construct a partial history of the time from a careful analysis of the adornments of the palaces and mansions of the chief actors in the stirring scenes of last century in French political life. Passing over the earlier periods of Henri Deux, Francois Premier and Louis Freize, we come to that of Louis Quatorze, a man who united a real desire to revive true art feeling with a debased and voluptuous mind. Progressing with the rise and degradation of his court, one is struck with the gradual development of the renaissance to a high pitch of perfection, and a gradual descent to a florid and meretricious travesty upon it. The reigning beauty in many cases exerted a marked influence on the work executed during her *regime*, and her original station in life might very easily be guessed from the decorations she indulged in. What is remarkable, however, is the originality and attractive character of most of the work. The delicacy of the decorations during the reign of Louis Quinze tells us of advance in refinement and a gradual abandonment of the virile renaissance in favour of the lighter and effeminate Italian styles. There is not apparent the same love of art for art's sake, but instead the gratification of the whims and fancies of a court that existed for the bubble pleasures of the hour. This period of dilletantism gave place to the pure and unaffected family life of Louis Seize, a bright spot of sunshine in French history, around which was hovering the storm of popular frenzy that had been brewed by Louis' profligate predecessors. The decoration shows itself in garlands of flowers, rustic scenes and other pastoral touches, especially in La Petit Trianon, the miniature palace of the unhappy Marie Antoinette. At the fall of the curtain on this tragic period, and following the accession of the great Napoleon, a remarkable change is seen in the houses of the nobility. Military rule produces severity in art as in other things, and we find the style of the First Empire beautiful, chaste, pure—but always severe. To-day there is a great revival of all these periods, and we have the fortunate advantage of choosing the best from each of them.

In working with copper pipe a difficulty is often met where lengths must be jointed to valves or fittings by means of flanges, because the joint between the cast flange and the rolled pipe cannot be made perfect. A device to mitigate this evil recently forms the flange casting with projecting lugs which comes up around the outside of the pipe, and thus increases the surface for the adhesion of the brazing material.

ONTARIO ASSOCIATION OF ARCHITECTS.

Mr. N. B. Dick, the late treasurer of the Association, who was elected to the Presidency of the Association during his absence in Europe and in spite of his expressed wish to be allowed to retire from office altogether for a time, has, since his return recently, written to the Registrar accepting the responsibilities of the position. The proposal to Mr. Dick came from the Council, by whom the constitution of the Association requires the election to be made, but during the discussion which took place in the Convention as to the feasibility of the election of the President being by vote of the convention, Mr. Dick's name was by general consent used in connection with the proposition.

* * *

The second annual examination of students was conducted at the School of Practical Science from Tuesday to Saturday, March 7th to 11th. The time of holding examinations was changed from April, in which the examinations were held last year, to March, as being more convenient to students who wish also to come up for examinations at the School of Practical Science later in the year. Before notice of the examination results is sent to the students who were examined it is necessary that the Board of Examiners report to the Council of the Association, in whom is vested the control of the examinations. The meeting of the council will be held as early in April as possible.

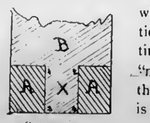
* * *

The Library of the Association has received a valuable addition in a set of *The Brickbuilder* for 1892 which has been presented by the publisher. The volume has been bound and is ready for lending. It is recommended by the Librarian as a practical aid to those who are aiming at good design in brick. The photographic reproductions are all of good subjects and there are many working drawings of standard examples in Europe and of work by the late H. H. Richardson and by well known American architects.

JOINTS IN CARPENTRY.

A most important feature of the manipulative or handicraft part of carpentry is the "joints" to be used in the work, and an accurate and practical knowledge of the principles relating to these is most essential. It is therefore proposed in this article to deal with some of the matters relating to this branch of the ancient calling, treating the subject generally, without going into the extensive question of special joints used in framing partitions or roofs. There are several kinds of joints used, according to the relation of the pieces of timber to each other. The "square joint" is when the pieces are at right angles with one another, and if the one is lying on the ground and the surfaces of the timber are even, a simple way of effecting a junction would be merely to rest or butt the end of the vertical piece upon the lower one, the pressure of material supported by the upper piece being trusted to keep the two together. Although often adopted, this form of joint cannot be relied on unless the pressure mentioned is great, and in a vertical position, that is, parallel to an imaginary line called "the axis" passing through the centre of the vertical piece.

The better method of making a "square joint" is by passing one piece of timber into another by means of a rectangular or square hole; this is well known as "the mortice or tenon joint," of which we give a sketch showing the junction in section. A denotes the piece of timber with an aperture 1234 called the "mortice" to receive the piece X called the "tenon," made in the timber B. This is a very common and useful joint, and in making same it should be remembered that the thickness of the tenon X should be well proportioned and about one-third of the width of the piece to which it belongs, in order that it may have sufficient strength. The depth of the tenon is generally equal to the depth of the piece to which it is joined. The mortice should be of the shape and dimensions of the tenon, smaller if anything, in order that no space be left when the tenon is inserted, and it should never exceed three-quarters of the thickness of the piece out of which it is cut, nor lose more wood than is necessary. When the tenon is sunk, or driven into the mortice the pieces are fastened by means of one or two wooden pins. This adds nothing to its solidity, but helps to keep the joint well together.



Sketch 1.

In order to prevent the possibility of these joints not fitting tightly, several improvements have been made on the simple method described above, as when the tenon is not made rectangular or square, but as shown in sketch 2, which is known as a "dovetail cut." Such mortices are very often not carried right through the entire depth of the timber, which is a good form of a joint to use when the strength of the timber will not allow much cutting away for a mortice. Another way to make a joint of this class is to carry the tenon through the mortice so as to have a piece projecting on the under side sufficient for a hole to be bored and a pin drawn tightly through it, thus keeping the tenon in the mortice without the aid of the pins as mentioned. A very satisfactory and reliable method is to combine the rectangular tenon and the dovetail mortice together, which is done by inserting the tenon and driving up wedges to fill in sides of the dovetail mortice.

Sketch 2.

Having thus far dealt with the "square joint," we will now consider what is known as the "vertical joint," that is, when two pieces of timber are joined, both of which are in the same vertical line. In most cases the joints under this head are practicable for joints between the timbers which are in a horizontal line, except for spanning; these methods not being calculated to be placed under such severe strains. As these joints are chiefly used for lengthening a vertical piece of timber by joining it to another, the principal point to be gained is to keep the jointed ends of the timbers from sliding or being pressed out. The pressure of the upper on the lower piece might be found sufficient to keep them together in a line, but it must be borne in mind that if the lower timber has no good foundation an unequal settlement will be brought about, and the line thrown out of the plumb; therefore vertical joints are very seldom made with merely even surfaces where they join, unless bound together with plates of iron, or bound round with iron hoop and straps securely fastened. A simple form of a vertical joint is made by cutting a groove in the centre of the end of each timber where they join, and a wooden or iron wedge inserted therein which will make it impossible for the lower timber to swerve from the plumb line, if it is securely fixed at its foundation.

It will be found, however, that there are other directions of possible pressure, and in order to provide against these, it is best to cut two grooves at right angles to each other at the end of the lower timber, and make two tenons on the end of the upper piece to join tightly into the grooves. This last form is by far the best, and although more labor is necessary, yet the safety that is secured is worth the extra work.

To join a horizontal to a vertical piece of timber at its extreme end, a good method is found by cutting a tenon in the upper piece and fixing it tightly into a mortice made in the lower piece, but by far the neatest and securest joint for this class of work is what is known as the "mitre joint." This is formed by cutting one piece of timber at an angle of 45° leaving a tenon in the middle, and cutting the other piece of timber at the end to the same angle making a mortice on the angular side to receive tightly the tenon of the other piece. If this work is done correctly it will be seen that the corner made by the two pieces will be at right angles.

The next class of joint it is proposed to refer to is the "horizontal joint," which is used in connecting pieces of timber crossing or meeting at right angles, and the method used is to lay one piece of timber upon the other and secure the two by means of wooden screw nails, but this form should not be used where there is much strain. A more satisfactory way is found by making a groove in the lower timber cut right across the width, and should be a little less in thickness than the section of the upper timber, that this can be tightly driven in. An improvement on this method is made by cutting a groove across the the lower edge of the upper piece and making a mortice to receive the upper piece, leaving a projection to fit into the groove made in the timber inserted. If this system is adopted it is impossible for the timbers to move even in their own directions.

When pieces of timber cross at an angle the method generally used to join same is by cutting a part out of the upper face of the lower piece large enough to receive tightly the upper timber, and these can be further secured by nails or pegs.

THE PLACE OF ARCHITECTURE IN NATIONAL HISTORY.

By G. F. Stalker.

Much greater rapidity marks the progress of history-making events, and greater minuteness and accuracy in chronicling the same, in our own time, than in any previous age. We have constantly "a chiel amang us takin' notes." It would seem as if the minute hand of the modern clock was provided with a fountain pen attachment, and that a faithful record of everything that transpired was most carefully registered for future reference. The daily and weekly newspapers, the monthly and quarterly magazines, the system of conducting the business of cities and countries, provide for the modern historian an abundance of material that is almost appalling. The situation in this respect, to-day, is a complete reversal of the state of things before the invention of printing; or even later than that, before the use of electricity. Old-time historians had a hard task of it, when, from the scanty material at their command, and the slow process of locomotion and intercommunication, they set about collecting and collating the events of their time. Add to this the laborious method of transcribing their tomes, the limited circle who could have access to them, and the most certain feeling that what they had been at so much pains to record would never benefit their own age, and it must be conceded that their occupation had at least none of the outward and visible signs of cheerfulness. And if their reward in their own time was, at the best, the most meagre, it has not, in all cases, been made up to them in the shape of unstinted posthumous fame and honour; for as we have waded through their works at school and college, the probability is we have bestowed upon them more maledictions than benedictions as our recompense for their hard and disinterested labors.

But if there is a law of compensation applicable, as some believe, to all things mundane, it is to this law that we are indebted for the durability of the materials on which the books of the ancients were written. The only perfect code of morals was written on tables of stone. Particular events in the lives of individuals, tribes and nations have been marked by cairns, pillars, obelisks and other memorial erections. Astronomical, mathematical and other discoveries, and historical facts have been cut in everlasting granite, while such writings as required more lengthened space were inscribed with indelible ink on parchments and papyrus prepared to run a race with time. (It is rather a singular coincidence in this connection, that Napier, the inventor of logarithms, worked out his problems on the garden wall of Merchiston Castle, near Edinburgh). And as the world advanced in age, these records became the subjects of study in the school, and were translated and transcribed indefinitely with more or less care. Naturally enough these translations were not free from errors; and the originals being almost inaccessible, and in some cases lost, it has been with great difficulty or altogether impossible that a thorough and accurate revision could be made of them. To this extent, therefore, the world has been a loser; for though nothing that is really good can be altogether lost, it may be shorn of much of its influence and beauty when we possess only a hazy idea of it.

Add to all this the fact that no historian ever yet wrote or could write without a certain bias, and the works of the ancient writers are subject to a considerable discount.

As regards the collection of materials the modern historian is infinitely better circumstanced than his old-time brother. The important occurrences in almost any part of the world may be said to be served up at the breakfast table of every household in civilized countries; and if we confine ourselves to any particular country, the difficulty that confronts the chronicler is not the paucity but the superabundance of matter. No need for him to scour the country in order to obtain data and information from every conceivable and inconceivable source. He has more need for the threshing machine than the reaper. So rapidly do events succeed one another, and so continually is the map of the world being remodelled, that it is no easy matter for the modern historian to keep pace with the times, and to separate the chaff from the wheat, so that what he records will be a faithful delineation of the events which really constitute the life of a nation. This, however, has never been accomplished; neither has it ever been attempted. The impossibility of the thing must be apparent to everyone on the slightest reflection.

To obtain anything like a comprehensive idea of a country we must have recourse to many channels of information. Its political life as a rule is recorded with greater minuteness than any other phase of its existence. And it is right that this should be so; for in those chambers where the nation's business is conducted, its laws are framed, and the multitude of interests affecting its internal and external affairs are brought forward and dealt with; so that, from the manner in which these things are done, we can form a very fair conception of the general character of a people. But though in the political arena there is, or there should be, nothing untouched which properly belongs to a nation's vitality, or which indicates its progress or retrogression, it would be absurd in the extreme to imagine that, within the limits of this one expression of national existence we have a full and complete portrait of the nation itself. The industries of the people, whose name is legion, can only be guessed at or catalogued by the laws which are made affecting them. But their extent, their application, and the manner in which they are conducted, all, in fact, that really constitutes the industries themselves, can only be understood or appreciated by reference to sources outside the political sphere altogether. And it is quite clear that written descriptions of the industries, amusements, and the general pursuits and occupations of a people must, in most cases, be inadequate; and to a stranger to the country, or even to the future generations of the country, such descriptions will inevitably be, to a great extent, cloudy or incomprehensible.

We have proof of this when we call to mind such points in the history of ancient peoples as have only come down to us in the works of contemporary writers. In connection with these we find the savants of our own time in a chronic state of disagreement with one another; and as time goes on the old writings are subjected to a process of re-translation, or the translations of a former age to a process of revision. Albeit, the one desire which animates all the scholars, is to obtain, in modern language, an exact account of the events which took place, and the circumstances connected with them, in ancient times.

In cases, however, where buildings were erected for any specific purpose, we are not dependent upon descriptions. The language of architecture is a universal language, and needs no such translations as are necessary in written documents. The accounts which they record are true and unbiassed, and can, therefore, be in all cases relied upon. This, of itself, is of immense importance, which is greatly enhanced when we keep in view the fact that, in ancient times, special training was prescribed for such as shewed that they had natural endowments or qualifications for making architecture or any of the arts their profession in life. The practice of art was, by the Egyptians particularly, considered as one of the highest religious avocations in which man could be engaged, and without this special training, which consisted chiefly of the study of music and form, no one was allowed to practice it lest they should be guilty of profanity or sacrilege. But even when such a rigorous system was not adopted to ensure its purity and development, architecture has, in all ages, found men of the highest attainments and the purest thoughts and aspirations to devote their lives to its study and practice.

The sentiment which at first induced men to commemorate events by the erection of cairns and pillars prevails to-day, only in a somewhat more pretentious form. It may be said that such erections are not now so monumental as utilitarian. In most cases this is a great advantage. Our memorial halls, institutes, hospitals, fountains and the like, may serve a very useful purpose, while they carry out the same feeling which has from the first animated our race. There is an inseparable, although it may be an indefinable, connection between an intangible historic event and an edifice to commemorate it; so that the milestones of history are being constantly raised all the world over, marking indisputably the progress or the decadence of nations.

But it is not merely works of a monumental character that give to architecture an historical importance. The ordinary everyday life, the business occupations and the amusements of the people are as clearly marked down in the domestic and civic buildings. In these, until we come to the time of the Romans, we have so few remains, that our knowledge is, of necessity, obained from such writings as have come down to us; and to whatever written source we may turn for our information we have to confess that the result is disappointing; whereas, from the Roman era until now, apart from any written descriptions, we are at no loss to understand the manners and customs and the occupations of civilized countries from the buildings which were then erected and are still extant. Our poets have peopled those old and ruined cities with the same old-fashioned, slow-going folk that used to inhabit them; have set them to work at their old occupations and household duties; have put their armies in motion against one another, and given detailed accounts of their methods of attack and defence, and with such minuteness of description that we might as well be reading an account of contemporary events. Even the distinctive racial characteristics are so strongly marked in their buildings that it is not difficult for the student of architecture merely to fix the date of the erection of a building, but also the race of people who erected it. So that the history of architecture is in reality a history of the world, and when compared with the sciences which treat of national or racial affinities, dealing, as it does, with the thoughts and feelings of men in all ages, its sphere is wider and more comprehensive, and its utterances more reliable and conclusive, than those of any other science yet known. To the historian, therefore, a knowledge of architecture is of the utmost importance; and on the other hand, to the architect a large acquaintance with history is almost indispensable. In the one case many of the leading points in history about which contemporary writers may give different and contradictory accounts, can be tested and set at rest, by reference to the inflexible testimony of brick and stone. In the other case the purpose for many features and details of buildings can be explained by hints or more lengthy descriptions of usages and customs which have long since become obsolete.

And as future generations will judge of the position which nations in the present day occupy in the civilization of the world by their architectural achievements, as much as, if not more than any other evidence, a most important responsibility is laid upon the shoulders of every architect. Unfortunately the same spirit which animated the architects in those times when the art was at its best does not seem to exercise dominion in the minds of those of our time. Neither are we influenced by surrounding circumstances to the same extent. We are too much inclined to imitate and reproduce what has already been done before, and that too, unhappily, without any very nice discrimination between what was good and what was bad in old examples. We are sometimes, also, inclined to forget that the design for a building for any particular purpose should have a very close relationship to that purpose and give unmistakeable indications of it. In this respect we are placed at a great disadvantage as compared with the ancients. There is practically no limit to the purposes for which buildings are required; and as in most cases these objects are peculiar to our time, and were never dreamt of in bygone ages, an opportunity is here afforded which should be kept in view.

It is frequently said by men who ought to know better, as they look at the magnificent cathedrals of the middle ages or the temples of a much earlier date, that the architects of to-day could not produce such work. Under present financial circumstances, certainly they could not. People are aghast at the wasteful expenditure of money if a large modern church should cost $50,000 dollars. But this amount has to be multiplied by one hundred before we get into cathedral figures at all. The same holds good in other classes of buildings. And we are not poorer, but much richer than they were, only they did not seem to think there was so much honor in having a long string of figures dangling after their names, as in spending their money for the public good. And the same penuriousness is observable in works of national character, and which are paid for out of the public purse; so that while architects have now a much larger scope for the exercise of their abilities, they are restrained and hampered by the very limited funds usually placed at their disposal.

The outlook, however, is much brighter to-day than it was a quarter of a century ago. There is a tendency among architects to break away from the old lines and to give to their general design and detail a character more in consonance with our own time. The fact also that architects are now expected to erect a very large building for a very small sum of money may not be without its beneficial results. If it forces upon us the observance of simplicity in everything connected with a building, it will have taught us one of the most essential qualities of true art.

SHAVINGS.

Messrs. T. E. Waller and H. G. Downer, plumbers, of Victoria, B. C. have assigned.

The Public Library Board of Toronto abolished the office of consulting architect at their last meeting.

Mr. Samuel Riding has been appointed sanitary-plumbing inspector for the town of Toronto Junction.

The corner stone of the extensive additions to the Collegiate Institute at London was laid on the 7th inst.

The Standard Drain Pipe Co., of St. Johns, Que., are increasing their capital to $500,000, and the new shares are being rapidly taken up.

The Imperial Portland Cement Co., of Montreal, is in liquidation, with liabilities about $70,000, and a poor lookout for the shareholders and creditors.

Large quarries of fine dark free stone exist in the immediate neighbourhood of Calgary. The stone is said to be easy to quarry and hardens by exposure.

Mr. Thomas J. Drummond, of Drummond, McCall & Co., Montreal, has been elected to represent the iron and hardware interests on the Montreal Board of Trade.

A clause providing that eight hours shall constitute a day's labour on all provincial and municipal works was voted down in the British Columbia Legislature recently.

Buildings to the value of $95,450 were erected last year in Berlin, which exceeds the amount of the previous year by $17,012, but in 1890 the sum expended was $103,825.

Mr. T. Hill, builder and contractor, of Truro, Nova Scotia, has taken into partnership Messrs. R. O. McCurdy and N. T. Wilson. The firm will be known as McCurdy, Wilson & Hill.

Messrs. Elliott & Son, of Toronto, have just completed a handsome stained glass window for the Central Presbyterian church, corner of Grosvenor and St. Vincent streets, Toronto.

Perfect cylindrical cores of rock formations overlaid by over 100 fect of water have recently been discovered in obtaining data for the new tunnel between P. E. Island and New Brunswick.

The new court house of Oxford county at Woodstock, cost $109,949. Mr. A. J. Brown, of Toronto, was the contractor, and there is a dispute over his bill of extras, which amount to $16,360.

A company known as the "Pacific Portland Cement Co." has been formed to operate the Portland cement industry near Victoria. Messrs. Travis & Co. are the agents, with A. S. Dumbleton as solicitor.

Messrs. Denis O'Brien & Son, contractors, of Montreal, have assigned, with liabilities amounting to about $17,000. The assets consist of plant and claims against Dominion Government and others for about $3,118.75.

In spite of the strong efforts put forward by Messrs. L. H. Davis, L. L. Beer and Benj. Heartz to obtain money sufficient to build a very necessary hotel on the island of Prince Edward, the scheme has fallen through.

During some boring operations of the piers in connection with some railway works at Brantford recently a valuable strata of marble was struck. A company is to be formed to start a quarry if investigations prove satisfactory.

Among the pictures to be exhibited at the World's Fair by the Canadian Royal Academy the one of Miss Mabel Cawthra, painted by Mr. Greer, and which was on view at the Royal Academy, England, is given the place of honor.

Contractor Webb, of Hamilton, is negotiating with the Board of Works of that city to purchase the quarry at the brow of the mountain. The city engineer and the street commissioner have reported against selling the property.

Mr. Ewart, the superintending architect in the erection of the Canadian building at the World's Fair, has received instructions to carry out the work of designing the enclosures and decorations for the Canadian Courts at the Exposition.

The captain of ships which carry brick have to be very careful. An ordinary brick is capable of absorbing a pint of water. So with a cargo of bricks in the hold, a serious leak may well go undetected, for the water that enters is sucked up as fast as it gets in.—*Clay Record.*

For more than 2000 years, a dressed stone containing 12,9 2 cubic feet—being 71 by 13 feet in size—has rested on pillars in a quarry at Baalbac, in Syria. It was intended for the foundations of the temple of the sun, a mile or more distant, to which four stones nearly as large were actually transported.

At the annual meeting of the Metallic Roofing Company, of Canada, Limited, held on January 16th last, Mr. E. Samuel was re-elected president, Mr. A. D. Benjamin, vice-president, Mr. J. O. Thorn, secretary-treasurer. The company are making arrangements to start a branch factory in Montreal.

A plan, with full information regarding the competition for the proposed memorial to the late Sir John A. Macdonald to be erected at Montreal, has been sent to Toronto for exhibition. Among the Toronto architects who propose taking part in the competition are Messrs. S. Hamilton Townsend, J. Wilson Siddall, Frank Baker and George R. Harper.

The Royal Academy of Arts, Montreal, have elected the following officers:—President, Robert Harris, Montreal; vice president, A. C. Hutchison, Montreal; secretary-treasurer, James Smith, Toronto; academician painter, John Hammond, St. John; academician architect, David B. Dick, Toronto.

A new company, with a capital of $10,000, has been organized in Hamilton to manufacture brick by a new process. Mr. W. A. Freeman, of that city, is said to have secured control of the product of nearly all the local brickmakers. The price of brick is now $6 as against $5 and $5.50 per thousand last season.

A company with a capital stock of $50,000, has been formed in Montreal named the "Bostwick Metal Lath Co.," for the manufacture and sale of laths composed of metal and plaster and other building materials. The company is composed of Mr. W. W. Bostwick, of New York, with Messrs. J. W. Allison, T. A. Morrison, J. H. Kendall and R. A. Mainwaring, of Montreal.

Mr. P. W. St. George, City Surveyor of Montreal, when reporting to his Board on the advisability of allowing steam to be injected into the sewers, stated that this was most injurious to health, for the steam displaced the sewer gases and forced them into the private houses. As there are no doubt connections of this kind existing in Montreal, it is hoped that speedy steps will be taken to remedy the evil.

Mr. J. P. M. LeCourt, architect, of the Department of Public Works at Ottawa, has recently had a romantic wedding in his family. His daughter was married to Mr. J. H. Stranger, of St. Anne de Manitoba. The couple met eleven years ago and never saw each other again until their wedding day, the engagement having been made by letter. The bridegroom's godmother stood in the same capacity to the bride thirty-six years ago.

A novel system of fire protection is in use in Cleveland, Ohio. Four 6 in. mains are laid from Cuyahoga River to the business streets of the city, covering a distance of 700 to 1,000 ft. The mains are provided at intervals with ordinary fire hydrants, and being laid with a fall towards the river they are normally empty. In case of a fire the city fire boat is run to the river end of the main with which one of its nozzles are connected. The pumping engines in the boat are capable of putting on a pressure of 200 lbs. to 250 lbs. per square inch, so a good pressure is available at the hydrants on the mains.

PERSONAL.

Mr. C. H. Rust, assistant city engineer of Toronto, has recently arrived home from a trip to England.

Mr. D. T. McIntosh, for many years with Messrs. Elliott & Son, Toronto, has resigned his position to enter into partnership with his father and brother in the firm of D. McIntosh & Sons, dealers and workers in marble.

The architectural firm of Darling, Curry & Co., Toronto, has been dissolved by mutual consent. Mr. Curry retires. The business will continue to be carried on by Mr. Frank Darling, under the style of Darling, Sproatt & Pearson, at the offices in the *Mail* Building.

We regret to announce the death during the past fortnight of Mr. Charles Gurney of the E. & C. Gurney Co., Hamilton and Toronto. The deceased, who was about 74 years of age, commenced business in a small way with his brother in Hamilton about 50 years ago. By perseverance the business was raised to the high position it now holds. He was a prominent and greatly respected citizen of Hamilton, and his large funeral on the 6th inst. in that city, bore evidence of the high esteem in which he was held among his fellow citizens, and large circle of business and private friends.

A good plan of preventing tools from rusting is the simple preparation employed by Professor Olmstead, of Yale College, for the preservation of scientific apparatus, and which he long ago published for the general good, declining to have it patented. It is made by the slow melting together of six or eight parts of lard to one of resin, stirring till cool. This remains semi-fluid, ready for use, the resin preventing rancidity and supplying an air-tight film. Rubbed on a bright surface ever so thinly it protects and preserves the polish effectually, and it can be wiped off nearly clean, if ever desired, as from a knife blade; or it may be thinned with coal oil or benzine.

QUESTIONS AND ANSWERS.

[Readers are invited to ask through this department for any information which they may require on lines consistent with the objects of the paper. The effort will be made to furnish satisfactory answers to all such enquiries. Readers are requested to supply information which would assist us in our replies. The names and addresses of correspondents must accompany their communications, but not necessarily for publication.]

W. T. B.:—Can you inform me which is the oldest architectural building of note in Canada?

Ans.—We would like to hear the opinion of some of our readers on this subject.

"CHIP":—What do you consider the best means of joining a principal rafter with a tie-beam?

Ans.—Provide the principal with a butting joint, made at right angles to the line of the principal and let into a notch cut on the edge of the tie-beam.

"OUTSIDER":—How can an architect join the Ontario Association of Architects? Where can I get full information as to cost, etc.?

Ans.—Write to W. A. Langton, Registrar O. A. A., Canada Life Building, Toronto.

C. D.:—What should be the scantlings of a roof covering a span of 54 feet, to be covered with slate?

Ans.—Tie-beam 12×7, queen posts 7×6¼, small queens 6×2¼, principal rafters 6½×7, straining beam 9×6, braces 4¾×2¾, purlins 8¾×5¼ and common rafters 4½×2. The pitch should be 27°, and trusses 10 feet apart.

The firm of Parkes, Reekie & Co., Montreal, mantels, tiles and other building materials, has been succeeded by that of Webster Bros. & Parkes.

OFFICERS OF TORONTO BUILDERS' EXCHANGE.

WE publish in this number, portraits of the officers of the Toronto Builders' Exchange, to the success of which we have referred on several previous occasions. These gentlemen were elected to office for the current year, at the annual meeting of the Exchange, held on the 16th of January last.

The President, Mr. W. Pears, is also Mayor of the town of Toronto Junction, and is connected with the Davisville and Carlton Brick Mfg. Co. He is well and favorably known, having lived the greater part of his life in the vicinity of this city.

Mr. Geo. Moir, the first vice-president, is senior partner in the firm of Moir & McCaul, carpenters and builders. He has for many years been identified with the building interests of Toronto, and is regarded as one of the most capable and reliable men in the ranks of the builders.

Mr. Geo. Oakley, second vice-president, represents the building stone interest, being a member of the firm of Oakley & Holmes, and president of the Master Stone Cutters' Association.

Mr. David Williams, the treasurer, who has been elected a second time to this office, is one of the oldest builders in the city, and a charter member of the Exchange.

The secretary, Mr. John L. Phillips, has served the interests of the Exchange for about a year in this capacity, previous to which time he was engaged in matters connected with the building trades. He has performed the duties of the office with singular courtesy and ability.

We have no doubt that under the capable management of these gentlemen, the Builders' Exchange of Toronto will continue to advance, and render valuable service on behalf of the building interests of the city.

CREDIT VALLEY BROWN STONE

From Carroll & Vick's No. 6 Quarry, Credit Forks, Ont.

SANDSTONE, fine grained, reddish brown. Contains quartz, and a little felspar and mica. The stone is in beds of four feet and under, and can be handled in pieces up to five tons. Quarry 300 yards from Railway.

Specimen.	Section under Pressure.	Height.	Crushing Load.	Crushing Stress per sq. in.	Average Crushing Stress per Square Inch
	Ins.	Ins.	Pds.	Pds.	Pds.
A	.....	.....	.....	.....	
B	2¾ × 3	2¾	131,000	15,188	
C	2⅛ × 3	2¾	130,000	14,751	
D	3 × 3	2¾	133,000	14,777	14,905

14,905 pounds is the average crushing strength per square inch of our Credit Valley Brown Stone.

The highest standard of test attained by any pure Sandstone in America.

IN confirmation of the facts above stated, we have pleasure in directing your attention to the accompanying table, showing the result of the test of our stone, in connection with the series of tests of building stones conducted in 1892 at the School of Practical Science, Toronto, under the direction of a committee of the Ontario Association of Architects.

By referring to the results of the tests above mentioned, it will be seen that the average crushing stress of the majority of Canadian and American sandstones is far below that of ours, the difference in our favor ranging from 75 to 50 per cent.

The Credit Valley Brown Stone, owing to its modest tone, harmonizes beautifully with red or cream colored brick.

It has been reported that there is difficulty in obtaining Credit Valley Brown Stone. To correct this mistaken notion, we wish to state to architects and the public that we have 40,000 cubic feet of stone ready to ship on the shortest notice, which can be followed up with an unlimited supply. Last year we made extensive additions to our plant and opened up new quarries and mines, and will supply promptly all orders given to us or our agents.

THE Association of Building Commissioners and Inspectors of the United States has resolved that buildings for the care of children and invalids should not be more than two stories in height, unless constructed of fire-proof material.

WE have to record another accident, with fatal results, due to the collapse of a derrick. This occurred on the 24th of March in connection with the new Wellington bridge in course of construction by the Dominion Government on the Lachine Canal, Montreal. Two workmen, Michael Owens and Timothy Gallivar, were killed by the falling of the derrick mast. As the result of an inquest to enquire into the circumstances, the jury suggested that the Government should employ more competent men on works of this kind.

IT is pleasing to note from a recent return made by Mr. E. Coatsworth, City Commissioner for Toronto, that there is a marked increase in the value of the buildings, especially dwellings, now being erected. In 1891 it appears from the report that the average cost of 1,100 houses built, was $2,700 each. While in 1892 the number of dwellings erected dropped to 529, the average cost was $3,000. It is a good indication of the thrift and frugality of the people of Toronto when out of the 30,000 dwelling houses now in the city, 50 per cent. of them are owned by the occupiers.

THE Victorian Institute of Architects announces three competitions. One, open to all resident architects in the Australian colonies under the age of 30 years, is for the best design for a school of art and picture galleries. The other two are for probationers and students of the members of the Institute. Additional interest in architectural matters and a more rapid development of architectural taste and skill would be likely to follow a movement of this character on the part of the Councils of the provincial Architectural Associations in Canada. The expense of one or two competitions each year would probably not be deemed sufficient, apart from other considerations, to prevent the attempt being made.

IN December last the Toronto Incandescent Electric Light Co. reduced their price to customers from one cent per hour to eight-tenths of a cent per hour for 16 c. p. lamps. This step, the company state, resulted in almost doubling the volume of their business. Thus encouraged they have announced within the last few days their decision to further reduce the price to six-tenths of a cent per lamp per hour. At this price incandescent electric lighting should displace gas in business establishments at least. It is said to be the intention of the gas company to meet this cut in rates for electric lighting by a corresponding reduction in the price of gas.

IN the matter of the dispute which has arisen in connection with the erection of the new city and county buildings at Toronto, application was made on the 4th inst. by Mr. Neelon (the late contractor) for an injunction to prevent these works being completed other than according to the order granted by the court September 10th last, which, it was contended on behalf of the applicant, allowed the work to be done only by day labor. An arrangement was come to by which the order referred to was enlarged so as to allow the work to proceed by contract and extending the rights of the applicant as relating to his action for damages, if the work was so carried out.

In our correspondence department this month will be found a letter on the subject of "tendering for works." No doubt this is an important question, and it would be well if a remedy could be found which would prevent the acceptance of tenders at figures below actual market prices, and from parties who have not much reputation to lose should they fail to satisfactorily carry out the works. There are difficulties, however, in placing this matter on such a footing as many contractors would prefer, and it is not an easy matter to interfere with the freedom of contract; nevertheless, contractors should be required to furnish good security for the due performance of their work. In this way the competition of incompetent and financially irresponsible contractors might be largely avoided.

The accumulation of snow and ice on the streets of Toronto has been greater during the winter which is about to close, than for many years previous. This, coupled with the fact that the Street Railway Company had barely time to get some of its lines into running order when winter set in, placed them at a serious disadvantage so far as preparation for keeping their tracks clear and maintaining an efficient service were concerned. Many of the citizens, appreciating the unusual difficulties against which the company have had to contend, have been both greatly pleased and astonished at the energy and skillful management by which a first-class service has been provided throughout the winter. It is safe to say that more serious difficulties are never likely to be met with in the future operation of the system.

There has been a substantial increase of late in the price of Canadian lumber, due to an increased demand for the same in the United States market. This should have the effect of increasing considerably the cost of building, but if we are rightly informed such will not be the case so far at least as Toronto is concerned. The greatly reduced volume of building enterprises during the last two years has given rise to excessive competition for such contracts as have been offered, and thus the advance in material is offset by lower tenders. We are informed that stone work is being done at eight dollars per toise, and brickwork, which a few years ago cost fifteen dollars per thousand, costs at present but eleven dollars. And this, notwithstanding that the price of labor has greatly advanced in recent years.

The fire losses in the City of Montreal during the first three months of the current year amount to upwards of half a million dollars. These losses, it is stated, will absorb three-fourths of the insurance companies' premiums for the year. So serious a condition of affairs has led to an investigation of the condition of the fire-protective appliances and of the fire department. As a result, the water pressure is declared to be insufficient, the pumping plant at the waterworks inadequate, and the fire department not up to the standard of efficiency required. The insurance companies have in consequence decided to advance rates 25 to 30 per cent. on certain classes of risks. This will no doubt lead to improvements being made which will lessen the opportunity for such destructive conflagrations as have this year visited the city.

Some architects profess to be able to see no advantages to be derived from connection with the O. A. A., and have withdrawn from membership therein. They appear to have overlooked or underestimated all benefits accruing from the Association to the profession, except such as might be computed in dollars and cents. This view of the subject must be admitted to be a narrow and selfish one. Notwithstanding, we have information which indicates that membership in the Association carries with it a certain monetary value. The Public School Board of a cerlain town in Ontario were about to erect a school building. Two architects sought to secure the work. The question was asked of each of them: "Are you a member of the Ontario Association of Architects?" The reply in one case was in the affirmative; in the other in the negative. The choice turned on this point, the Board at once selecting the architect who was a member of the Association. They required some guarantee as to the competency of the person they would employ to carry out the work, and membership in the O. A. A. was considered sufficient.

It has been universally acknowledged that there is greater economy in machinery as compared with hand labour, but the application of motive power to the various branches of joinery has not been extensively appreciated. It is impossible to overrate the value and importance of machinery in joiners' shops, yet the use of such machinery can be overdone. A proper number of machines is most essential, but four machines will be generally found sufficient, viz: a portable deal frame capable of sawing at one time two deals (14x4) into boards of any required thickness, a self acting saw-bench, a planing machine, and a general joiner which will do all the necessary working tenoning and such work usually executed by hand. These machines can be worked by a 12 horse power steam or electric motor, and, if solidly fixed on stone bases, they can be driven at a great speed without vibration. There seems a general idea that machinery can only pay in very large establishments, and unless a builder can have separate machines for each operation he had better be contented with hand labor. But we are lead to believe that every man having a thriving business would find a great saving could be effected by a moderate outlay on machinery of this description.

It is a frequent subject of complaint on the part of successful architects that features of their designs which have been thought out at the expense of much time and mental effort, are appropriated by persons claiming to be architects, but who are without the ability or disposition to evolve original ideas of their own. An effort was recently made by the Ontario Association of Architects to secure under the Copyright Act protection for the authors of architectural designs, but it was found not to be practicable to do so. Our attention was recently called to a case of pirating which will serve to illustrate the audacity of those engaged in the business. A Toronto architect recently met the officials of a church in a neighboring town, who had under consideration the erection of a new edifice, and was shown another set of drawings which had been submitted. These proved to be an exact tracing from one of his own designs. A copy of the Canadian Architect and Builder in which the design was published a couple of years ago, has since been forwarded to the building committee. It is a satisfaction to know that in this instance at least the pirate has unintentionally played into the hands of the architect the reward of whose labor he sought to reap.

At the recent convention of the National Association of Builders a member introduced a resolution providing that means be taken to secure the affiliation of the Canadian builders' exchanges. The secretary is reported to have moved in amendment that action on the resolution be deferred until after annexation. This, from the Canadian standpoint, will be taken to mean that the question has been shelved

"It may be for years
or it may be forever."

The principal advantage to be derived by Canadian builders from affiliation with the National Association would be the opportunity afforded them to learn the benefits to be secured from a Canadian organization, and the lines upon which it might be successfully conducted. It would be impossible for more than perhaps half a dozen Canadian delegates to attend the conventions of the National Association, and being so few in number, they could not expect to exercise much influence or secure proper consideration of questions affecting the building interests of this country. For this purpose there are required Canadian Associations for the different provinces which should meet semi-annually or annually as do the Architectural Associations of Ontario and Quebec, to consider legislation, forms of contract, prices for labor and other matters of like importance affecting the building interests. The Toronto Builders' Exchange, which is itself an example of the benefits accruing from local organization, might well take the iniatory steps to bring about the formation of a provincial association.

It is said that the City of Toronto has as great an extent of shop fronts as the cities of Buffalo, Detroit and Rochester combined. Toronto is said to have 27 miles of shop fronts, while Buffalo has only 13 miles. Circumstances are at work in Toronto, which will probably largely transform the character of some of the principal thoroughfares, such as King and Yonge

streets. On these streets there are at present a large number of small shops which it is believed will before many years revert to residence purposes. Two principal causes are at work tending to bring about this change. One is the introduction of rapid electric street railway transit, by means of which residents in the outlying districts of the city can be transported to the business centre within an interval of a few minutes. These facilities for dealing at the larger down town establishments is likely to be taken advantage of to the detriment of the smaller business concerns on the less important thoroughfares. The second cause is the recent development of a few large establishments where goods of almost every class are sold under one roof. These concerns will certainly wipe out of existence a very large number of the smaller stores. It is estimated that one such establishment already in existence in Toronto, is doing the trade which formerly was divided amongst 500 small stores. These changes must seriously affect the value of a large amount of property now used for business purposes.

Not more than five or six years have elapsed since the manufacture of pressed bricks was commenced in Canada. In that brief period, however, the manufacturing firms have multiplied from one to half a dozen, and the process has been perfected to a wonderful degree. In point of hardness, closeness of grain and perfection of form, the pressed bricks at present being manufactured in Canada will compare favorably with those in use anywhere on the continent or abroad. They are also being produced in a pleasing variety of color. In view of the success which has been achieved by the manufacturers, it is with much regret that we have observed the otherwise excellent effects obtained by the use of this material, well-nigh destroyed in the case of some important buildings recently erected by the efflorescence or lime-like exudation which, working its way through the pores of the bricks, forms a deposit on the surface. So detrimental is this to the appearance of the building, that unless means can be found to avoid it, architects will no doubt feel compelled to cast about for some other material. We learn that the possibility exists of determining in advance of their use, whether or not bricks will effloresce, and at the royal testing station of building material at Berlin, the test has been applied. The process is described as follows: The bricks are gradually heated to the boiling point in a waterbath, and are then suddenly immersed in cold water. They are boiled for one hour in a 16 per cent. solution of common salt and frequently cooled as before. They are again boiled half an hour in 5 per cent. soda lye. They are further boiled half an hour in the same solution, with the addition of 1 per cent. of ammonium sulphate. They are then boiled half an hour in a solution containing 2 per cent. blue vitriol and 10 per cent. common salt. Fragments of the brick are placed for 75 hours in 3 per cent. hydrochloric acid and for 50 hours more in 5 per cent. hydrochloric acid. By further treatment of the fragments with pure 4 per cent hydrochloric acid a fluid clear as water is formed, which, when treated with barium salts, should not show the presence of sulphates which are the cause of efflorescence. These tests determine the quality of the brick as well, and none which fail to stand the test should be allowed to enter into the construction of a building. We hope that the manufacturers of pressed brick will see the advisability of endeavoring to overcome the objectionable feature of their material to which we have referred.

By order of their leaders seventeen hundred carpenters employed on the construction of the World's Fair buildings have gone on strike. This action was taken because a request for an advance of wages from 35 to 40 cents per hour and the dismissal of all non-union carpenters, met with refusal. The extremity of those upon whom rests the responsibility of getting things in shape for the opening of the Fair, five weeks hence, is regarded as the labor agitators' opportunity, and is taken advantage of to the fullest extent. The utter selfishness which under such circumstances prompts the unions to attempt to snatch a slight advantage at the expense of thousands of exhibitors and others who have large business interests connected with the forthcoming exhibition, deprives them of the sympathy which the public would accord to legitimately conducted efforts for the improvement of the conditions of labor. In this connection, mention may be made of decisions recently given by judges Taft and Ricks of the United States Circuit Court, which are likely to exercise an important bearing upon strikes of workmen employed upon works of a semi-public character. In the case of a dispute between the brotherhoods of locomotive engineers and firemen, and the Toledo, Ann Arbor and Northern Michigan Railway Co., Judge Taft granted an injunction restraining the chiefs of these organizations and the engineers and firemen from in any way, directly or indirectly, endeavoring to persuade or induce any employees of the railway companies whose lines connect with the Ann Arbor not to extend to the said company the same facilities for interchange of interstate traffic as are extended to said companies by other railroads. Eight employees of the company, after the issuing of the injunction, at once resigned their positions on being ordered to take out cars containing Ann Arbor freight. Judge Ricks, on being appealed to, ordered the arrest of these men for contempt of court, and in addressing them said:—"This court does not assume the power to compel you to continue your service to your employers against your will, but it does undertake to compel you to perform your whole duty while such relations continue, and does further claim for the purpose of ascertaining whether its orders have been violated, the right to determine when your relation to your employer legally terminated, and when your obligations to observe this order cease." This decision has caused a commotion in labor circles, mass meetings of unionists having been called in New York and other cities to discuss it. Whether or not the conditions upon which it is based would be held to apply to the World's Fair dispute is as yet an open question.

BRICK PAVING.

This subject has become of great interest in Toronto on account of the City Engineer having recommended that vitrified brick should be used in future for paving the streets of the city. The advantages claimed for this class of pavement are cleanliness, freedom from noise, sanitary perfection through the bricks being non-absorbent, smoothness, with a good foothold for horses, durability, if made with proper materials, and its price, which will compare favorably with other kinds of roadways. A great difficulty in this work is obtaining the necessary uniformity in the hardness of the bricks, which should always be burnt until a homogeneous section is secured throughout each. If this is not done, the first frost will determine the inferior bricks, and the moisture absorbed by such will freeze the bricks and cause crumbling and cracking through expansion.

In the manufacture of bricks for paving purposes the clay to be used is a very important matter. It should be able to withstand a sufficient amount of heat, without fusing, so as to render the bricks hard and impervious to water; but while so much depends upon its refractory nature, reasonable fluxing agents are necessary to make the clay adhesive. It should also be of shale rock nature, so hard in its bed that blasting becomes necessary to remove it. Silica and alumina should constitute the chief refractory parts, but there should not be an excess of the former, as it possesses no binding properties, and bricks made from such clays are rough, and senacious. Potash, soda, lime, magnesia, iron and other elements will be found in small quantities in clays suitable for pavements, and these impurities give a tendency to fusion according to the amount present. Such ingredients should therefore not exist to any large extent; especially is lime to be avoided, as the heat used in firing the bricks will bring about a caustic lime which will absorb moisture when the bricks are laid as a pavement. Iron will make the clay fusible if over 6 to 10 per cent. of the clay is this metal. It is the presence of iron that changes the colour of the brick from that of those made from ordinary clays, and is therefore easily detected. Fineness of clay is most essential, and when this is the case, care only is needed in the manufacturing process to secure good bricks, that is, provided the clay is sufficiently refractory. Coarse clay will require more heat before vitrifying, but the finer the brick earth is ground, the stronger and harder the bricks will become.

The process of manufacture is a difficult problem, and very different from the usual one of brick making. A system that works successfully in one place, will not prove so elsewhere, on account of the diversities of clays. In no case should admixture be employed.

It would be impossible in this short article to describe all the

different methods used in the States to make paving bricks, but a very common one is by using, with modifications, the plant commonly employed for tile making. Taking one case in the United States as a general example: where a brick-maker burns out 1,600 bricks an hour, the system in vogue is along the lines referred to. The clay from the output is delivered to a Blake, when making this kind of brick, and finished with a dry-pan crusher. It then passes to a tempering machine, and is then forced through the desired mold in long lengths, afterwards being cut with a wire by hand to its proper size. The bricks are then removed to a drying house and left until ready for burning. The ordinary kilns are not used, the bricks being packed close together in cylindrical kilns with hemispherical tops giving a down-draught. They are burnt from 70 to 80 hours in a heat sufficient to cause tin to melt and copper to run together. It is here care should be taken that the bricks do not become fusible.

When laid on a good concrete foundation, and the joints well filled in with pitch or tar, a vitrified brick pavement will stand a crushing strain of over 8,000 pounds to the square inch. The result of some tests in the United States from paving laid with bricks, and others laid with ashpaltum blocks, limestone, or granite are very interesting. The samples were weighed before and after being laid and tested, which was carried out by means of a waggon going over the pavements sufficient to amount, it is supposed, to 9½ years traffic. It was found from this performance, that the abrasion of the brick paving was 9%, the asphaltum blocks 14%, limestone, 10%, while on the granite it was hardly noticeable.

Turning to the cost of this pavement, if used in Toronto, we find that unless the Canadian brick merchants can manufacture good material, the cost of obtaining same from the United States, would bring the price far above that of asphalt. But, if the necessary brick can be made here, such paving laid on a proper concrete foundation should not cost more than $2.30 per yard super., and if a sand instead of a concrete foundation is used, then the price should not be above $1.50 per yard super., but this latter class of work cannot be recommended where traffic is heavy. The present price of asphalt is about $2.60, and cedar block paving can be laid for 70c. to 80c. per yard super. The above prices for brick paving therefore compare very favorably with these. As already stated some of the brick merchants in the suburbs of Toronto are putting in the necessary apparatus for making paving bricks, believing that they have the proper clay in their land to turn out good, durable and uniform material. If this is so, and provided the process of manufacture can also be perfected, there is no reason why vitrified bricks should not be largely used throughout Canada for paving purposes.

VAULTING.

It is interesting to trace the methods of vaulting used among masons at different periods in order to meet the requirements of the architecture of their respective times. This is not only a matter of antiquarian interest, but is an essential knowledge to those studying the art of stone cutting, because, where circumstances will allow, the architectural buildings of the present day follow the styles and orders introduced by the ancient architects.

We learn from ruins still existing that the construction of vaulting was known in the earliest periods, vaulted arches being found amongst the ruins of Nineveh. There is no doubt, however, that this class of work was not employed to any great extent before the Roman era, and even in buildings at this time there is no evidence of scientific knowledge of stone cutting. For instance, if two vaults, of the same height at the crown, but of different spans, are to be made to intersect each other, the method now used is to get the profile of the groin by ordinates; this does not however appear to have been practised by the Romans. Their way of carrying out such work was to start the springing of the lesser arch, making the sections of both vaults of different radii, which left the groin a wavering line. The crowns of these arches were always level, and this prevailed until more complex forms of arches were introduced. The early Norman vaulting was carried out on the same principle as those existing at Rome, being distinguished by its semi-circular arches. This changed however with the introduction of rib work, which then consisted of a frame work of light stone ribs, filled in with courses of stones cut to fit the spaces between the ribs. Although this arrangement was in common use at the time, yet some of the buildings of that age show the introduction of the modern method of making the profile of the groin dependent on the form of the principal arch. During the middle ages ribbed vaulting may be said to have been divided into three forms:

(1) Plain ribbed vaulting, which sometimes had ridge ribs, but was frequently without. These arches were often decorated with paintings, and were much used in French and Italian churches of that time.

(2.) Lierne vaulting, in which the ribs were very numerous, and did not always change the direction of the vaulting surface as in the previous class. These arches, often richly decorated, required a thorough knowledge of projection, and although the work at that time was not probably done by any regular geometrical method, yet the natural power the masonic artists had of conceiving in their mind what they wished to carry out, greatly helped them in their work.

(3.) Fan vaulting seems to have been confined entirely to England. The main ribs in this work had all the same curvature, and very often this class of masonry was found alongside lierne vaulting in the same building. The complex forms of this class became so numerous, the panels so small, that it was found better to build all the vaulting by jointed masonry, the panels being sunk into the undersides of the archways instead of being beded on to the ribs. Henry VII Chapel at Westminster Abbey is built entirely in this way.

Stone cutting, as an art, attained its greatest development in the 15th century, but although the work gained as large amount of perfection in Italy as elsewhere, yet the Roman rounded style of vaulting as mentioned, was never entirely superseded. The great master-piece of the Italian work in vaulting is, beyond a doubt, the dome of St. Peters, at Rome, although defective in form in some points. It was built at the close of the 15th century from the designs of Michael Angelo, and the work is an acknowledged specimen of the successful application of stone cutting to domes.

During the building of this cathedral a celebrated French architect, Philip De Lume, published the first book containing a complete system of lines for stone cutting. From the opinion expressed, it appears that ribbed vaulting had fallen into disuse, but he acknowledges the extraordinary evidences of mechanical skill displayed in vaulting executed by the Italian masons, to which subject reference has already been made.

There is little worth noticing in the progress of the history of this art from that time to the present age, most of the works of stone architecture being copies in construction from the old schools. The vaulted roof of St. Paul's Cathedral, London, shows the architect's thorough knowledge of his work, but the building has only a wooden dome, which is merely a picturesque addition to the structure, not an essential part of the construction. Although there were no remarkable changes, yet masonic art became a necessary study for the architects of the day, and geometrical projection formed an important part of education in the profession.

It would not be proper to close this short historical sketch of vaulting without referring to the introduction of oblique arches for skew bridges. They have come to be used only during the last thirty years, and no doubt the development of railways made a necessity for such bridges for before they were introduced, the railway tracks had to be so arranged that all rivers and roads crossed at right angles which meant much unnecessary expense.

To-day, in Canada and elsewhere, the mason does not obtain many opportunities to carry out his art to advantage, but as the country develops and the fine arts become more appreciated and studied, ancient architecture will revive as it has done before; then artistic stone masonry will take its place again among the chief architectural features of our large buildings.

The second copper covered statue of the group of twenty to adorn the new St. Peters cathedral, Montreal, has been completed by Mr. Grattor. It represents St. John the evangelist.

Three large blocks of granite of an aggregated weight of a little over twelve tons have been shipped from one of the up river quarries to Ottawa to form the base of the monument to be erected in the Parliament grounds, Ottawa, to the memory of the late Sir John A. Macdonald.

THE NEW PARLIAMENT BUILDINGS OF ONTARIO.

On the 4th of this month the new Parliament Buildings at Toronto were formally opened. It naturally occurs to us in chronicling the event, to consider what sort of bargain the people of Ontario got for their $1,200,000 odd.

The general scheme seems proper. The Legislative Chamber is in the centre, over the main entrance and approached by the grand staircase. This gives the central motive which, from its singleness of purpose, lends itself to effective composition on the exterior. The offices of the Legislature and of the departments extend on each side of the centre and along wings which return northward, finishing with a stack of lavatories at the end of each. That is the plan in simple, and it seems a straightforward plan in the usual manner of public buildings where a general scheme rules, and rooms are apt to be proportioned by position rather than use. But in the main feature of the interior arrangement there has been a judicious expenditure of space which makes the inside of the building fine, and is worthy of all praise. The grand corridor which runs the entire length of the building from east to west, is made of sufficient width to have on each side of the central portion (where the grand staircase landing intervenes) a space open from the ground floor to a skylight in the roof. The passages of the upper floors thus take the form of galleries at these points, and on the ground floor the corridor has on each side a colonnade which supports these galleries and their arcades. The colonnades, the open space, the light from above, all combine to redeem the corridor from the dark and dreary monotony that is so often all the architectural effect presented by the passages of a great public building.

Thus far we may perhaps assume the architect, but we are afraid it is too obvious that the person with whom we have had to deal for the carrying out of the plan is not so much the architect as the architect's draughtsman. We have no doubt the draughtsman did his best, we would impute to him nothing but righteousness, but surely the architect's commission was sufficient to afford a draughtsman who could design. In this same corridor which we have described, there is but one set of columns to be repeated along the whole colonnade. The detailing was limited, and with a little careful study in the hands of one who knew something might have been carried to perfection and made the whole corridor beautiful where now the details are poor on the ground floor and offensive in the upper storeys. On paper this essay of an apprentice in columnar details would be something to smile at, but that they should be actually erected in an important public building is a matter rather for indignation. The same may be said of the grand staircase. It starts fairly well in iron and slate, but above, where we get to the region of arcades, and what we may suppose to be intended for an ornamental ceiling, the draughtsman's efforts should not have been allowed.

The Assembly Chamber, the grand piece of the design, shows more skill in the designer, but we are afraid cannot be said to satisfy good taste. There is some well executed wood carving on the floor of the House which really gives pleasure and is of the more value as being different in type from the style we have become accustomed to of late years.

Of the exterior we are afraid there is little good to be said beyond praise of the material. It is a fine mass of Credit Valley brown stone and as such cannot but look important.

It is not, however, of meanness we have to complain. The central pavilion with the main entrance, the 16 feet unmullioned windows of the Legislative Chamber above, and the enormous roof which crowns it, is certainly striking. But its proportions are swaggering rather than dignified. Perhaps its self-assertion may be intended to represent the idea of provincial antonomy, but we must confess we should have preferred to have complimented the idea by representing it with a little more of the dignity of beauty.

The roof of this central pavilion is a fine and bold erection, but it seems to us a pity that it was not constructed of iron, so as to save at least the danger of fire originating within its own limits. As it is, being a forest of timber above the highest cast of the hose, its existence is a menace to the public documents below, and the public may perhaps some day wish it were away. As for the other roofs, we must candidly say we wish they were away now, especially the eccentric hipped roofs with glass tops over the main building on each side of the centre. They must form capacious snow traps at the junction with the other roofs. But our discontent is chiefly with the question of beauty of form, and with the draughtsman's apparent indecision as to what pitch to adopt. If the buildings had been planned for a long ridge instead of these pyramidal forms with glass apexes, the front would have been much helped, and the glass might have shown only on the rear—the long suffering but picturesque rear.

But the glass is a friend giving the top lighted corridors within, and we should have been glad to see more of it if the architect had availed himself of it to a greater extent so as to reduce the size of the windows on the facades.

It is these which really spoil the building. They have not even practical advantage to recommend them. The corridors are lighted chiefly from the top, and could be given more light from that quarter and from the rear. For the offices themselves, windows of such a size are a great discomfort. The mere operation of lifting a sheet of glass 9 feet wide is found to be troublesome. In winter the rooms must be pervaded by the sun to a painful extent, and in summer also it will probably be necessary to keep the blinds down and exclude air as well as sun. With windows on a more reasonable scale there is more chance of compact and well arranged planning of the offices, as there is greater freedom offered for the disposition of partitions. The draughtsman too, with more reasonable windows, might have suffered less defeat on the exterior. As it is he has been unable to make anything of it. The conditions were hard, and he does not seem to have been skillful. Where he erred he erred no doubt from ignorance; but this same ignorance, how much has it cost us? Draughtsman is writ large all over our greatest and most costly public building.

ONTARIO ASSOCIATION OF ARCHITECTS.

As the meeting of the Council at which the report of the Board of Examiners is presented will not be held until after we go to press, the results of the Association examinations held this month cannot be published in this number.

PERSONAL.

Messrs. Dick & Wickson, architects, Toronto, have removed their offices to No. 34 Canada Life Building.

The widow of the late W. G. Storm, R. C. A., died in the Presbyterian Hospital, New York, on the 28th of March.

Mr. W. E. Doran, architect, of Montreal, is a candidate for the Presidency of the St. Patrick's Society of that city.

We are pleased to record the marriage of Mr. H. J. Powell, architect, of Stratford, to Miss Minnie Venton, of the same city.

Mr. Robert Weddell, contractor, of Trenton, is to contest West Hastings in the interests of the Conservative party at the next provincial election.

Mr. S. G. Curry has returned from British Columbia, having fulfilled his duties as expert in the competition for the Government Buildings at Victoria.

Mr. James Battle, cement manufacturer, of Thorold, is mentioned as a probable candidate for Parliamentary honors, in the Conservative interest.

Mr. D. T. McIntosh, on severing his connection with the firm of Elliott & Son, Toronto, was presented with a handsome piece of bronze statuary by the firm, and a gold-headed cane by his fellow-employees.

Mr. Montague Castle, of Montreal, is a winner of a first and second prize in a competition for the best life drawing open to all American Students in Paris. The prizes were given by the President of the American Artists' Association of Paris.

Messrs. Cassels, Percy Over, and C. H. Acton Bond, well known Toronto draughtsmen, are at present in St. Johns, Nfld., assisting Mr. J. A. Pearson, of the firm of Darling, Sproatt & Pearson, who has a large amount of work under way in that city.

Mr. Coste, Chief Engineer of Public Works, advocates the use of creosote for timber used in crib work and piling. It no doubt is a great preventive of the sea worm eating away the timber. As all the specifications for Government works of this class provide for all piling and crib work to be creosoted, there should be an opening for an enterprise along this line in Canada.

COMPETITION FOR GOVERNMENT BUILDINGS AT VICTORIA, B. C.

The experts in the above competition have given their decision in favor of the design submitted by Mr. F. M. Rattenbury, of Vancouver. The five sets of plans submitted in the final competition were thoroughly analyzed by the experts under the several heads of "Entrances," "Staircases and Passages" "Design and Composition," "Light, Air, Lavatories," "Construction," Detail," "Heating, Ventilation and Drainage"— the principal heads on which the award was based. As the result of this analysis, the designs were placed in the following order of merit :

1—"For our Queen and Province," (F. M. Rattenbury, Vancouver, B.C.)

2—""Spes Labor Levis," (T. C. Sorby, Victoria, B.C).

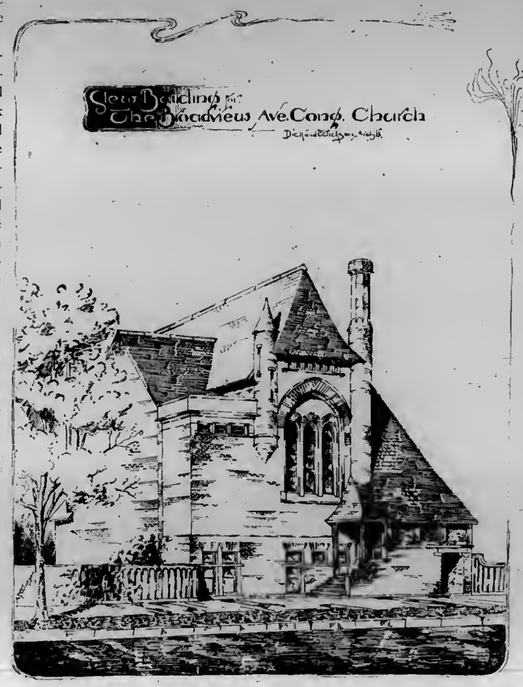
3—"Caractacus," (F. M. Garden, Chicago).

4—"A Red Seal," (J. M. Corner, Boston, and W. P. Skilling, Seattle).

5—"Dieu et Mon Droit," (J. Francis Brown, Toronto.)

The following particulars regarding Mr. Rattenbury's design, which is in the Classic style, are given in the Victoria *Colonist* :

The buildings are arranged in three groups—the centre or principal building comprising six departments so arranged that, whilst each of the three wings will be a perfect and complete building that can be erected independently of the others, they will when completed form a monumental and impressive pile. The grand entrance in the centre of the facade leads into a central octagon hall, terminating in a nobly proportioned dome. From this octogan hall on the ground floor the Minister of Education's department is approached on the left ; the Treasury on the right, and the Lands and Works department in front. On the first floor the same arrangement is repeated with the Provincial Secretary's department on the left, the Attorney-General's department on the right, and the legislative hall and offices in the centre. Thus from this one hall is every department immediately approached, all confusion or perplexity being entirely obviated. And while each department thus forms part of one central scheme, it has nevertheless its own independent entrance, staircases, strong rooms and lavatories, rendering it a perfectly contained and independent block.



The grand entrance is a handsome enriched portal, approached by a grand flight of steps. Through this the visitor enters the dome, which ultimately may be enriched by sculpture, mosaics and decoration. A flood of light is shed down from the cupola at the apex. On special occasions the entrance can be reserved solely for the legislative hall, the departments on either side having their own special entrance as before described. The legislative hall is situated in the centre of the block and has a corridor round it with a belt of rooms for the use of the ministers and members, committee rooms, library, etc.

The hall itself is a spacious and beautiful room. On three sides an arcade is carried round, with galleries for the public, ladies and reporters obtained over the corridor.

On the third floor the Lieutenant-Governor has a suite of rooms in front, facing James Bay and approached by the elevators next the principal entrance.

An unique and ingenious method of protecting the building from fire is adopted. At the approach to the three departments on each floor from the central hall, a system of iron doors or bulkheads is arranged, so that in case a fire might occur it can be isolated to one wing and controlled, without there being any possibility of its spreading. The heating and ventilation are also carefully considered. This is the principal block. Two others, perfectly fireproof, one on each side, are arranged for the Land Registry office, on the right, and the Government Printing office, on the left. The two detached buildings at either side stand somewhat in advance of the principal building—looking on the plan somewhat like the three sides of a square. These are connected to the main structure by a colonnade of columns, forming a covered approach from one to the other.

The winner of this competition is a young man under 30 years of age, who arrived in British Columbia from England about a year ago.

We hope to be able to publish at an early date a reproduction of the accepted design, and also of some of the other designs which were submitted.

TREATING STONES FOR CONSTRUCTION.

ARCHITECTS have lately called attention to the desirability, in the case of stone that is to be used for important purposes, that it be quarried, stored and seasoned for some time before being hewn and placed in the walls, the natural sap being by this means allowed to evaporate and the stone tested as to its quality ; it is admitted that this method would add to the cost, but that the money would be well spent, if this precaution prevented the wasting of such stones by rains, frost or atmospheric influences, which, especially in cities, soon act on the surface of a newly quarried stone. On the other hand, stone that is quarried one day and built in the next is in a green state, and must be considered unfit for use ; that it, it is not in condition—it is at its weakest—its pores are open and ready to absorb not only moisture but the gaseous and disfiguring influences which tend to its destruction. It is well known to every hewer that to get a polished surface on a stone that has lain for some time is very different from what is obtained on one fresh from the quarry—a fact which of itself is regarded as sufficient evidence to warrant the course recommended, namely, to thoroughly season the stone before using.—*Builder and Woodworker.*

The Ottawa Institute of Architects has elected the following officers for the ensuing year : President, D. Ewart, of the department of public works ; vice-president, F. J. Alexander ; sec.-treas., G. M. Bayly ; council, Messrs. J. W. H. Watts, J. G. Grist, K. Arnoldi and M. C. Edey.

The Stonecutters' Section of the Toronto Builders' Exchange, have appointed their officers for the year as follows : President, J. Vick, of the firm of Carroll, Vick & Co.; vice president, Fred. Brown, of the firm of Brown & Love ; treasurer, John Barnard, of the firm of Walker & Barnard ; Secretary, G. L. Phillips ; Auditors, G. Oakley and R. Smart.

QUESTIONS AND ANSWERS.

[Readers are invited to ask through this department for any information which they may require on lines consistent with the objects of the paper. Every effort will be made to furnish satisfactory answers to all such inquiries. Readers are requested to supply information which would assist us in our replies. The names and addresses of correspondents must accompany their communications, but not necessarily for publication.]

"Country Builder": Do you know where I can get patterns for scroll work ?

Ans.—There are few firms who keep these goods. Messrs. Rice, Lewis & Son, King St. E., Toronto, can supply you.

T. W. B.:—Are there any other builders' exchanges in Canada except those at Toronto and Winnipeg ?

Ans.—We understand there are exchanges at Ottawa, St. Catharines and St. Thomas. Mr. Phillips, Secretary of the Toronto Exchange, might be able to give you further information.

A. B.:—Can you tell me through your columns the best way to stain wood grey ?

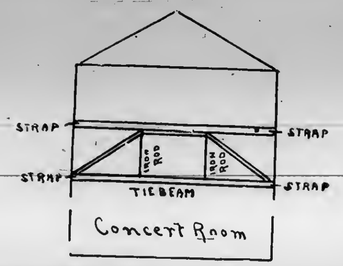
Ans.—Apply a solution of one part silver nitrate in 50 parts of distilled water. Follow this with a coat of solution of ferric acetate until the proper shade is obtained. Do not let this preparation touch the hand.

G. F. S.:—Will you kindly inform me where I may obtain printed instructions and information relating to the competition for designs for the improvement of St. Lawrence Market, Toronto, recently advertised in your weekly edition ?

Ans.—We learn upon enquiry that there exists no printed information for the use of architects in relation to this competition. In fact, as we pointed out on a former occasion, the whole matter is in too hazy and indefinite form to warrant architects in having anything to do with it.

"H. E. Gates, Dartmouth, Nova Scotia" :—I am planning a 3 storey wooden building, the first storey of which is to be used as a concert hall. Please inform me of the best means for supporting the other floors, as I do not wish to use iron columns ? The building is 40 feet wide.

Ans.—You give no data from which we can gather what the upper floors have to carry. But in describing the building as being wooden, you suggest the advisability of spreading the weight of the upper storeys over many points, and that the best form of support would be girders twelve feet on centres or less, as necessary, so that they may be not too deep to form an agreeable beam finish for the ceiling of the concert hall. Another method would be that shown in the accompanying sketch if the partitions on the upper floor will permit.



Unless very carefully done, with a surplus of strength, it is but an undesirable make shift.

"Young Plasterer": From what cause does Plaster of Paris set so firmly when water is applied to it?

Ans.—Plaster of Paris derives its name from the fact that it was first made for commercial uses from a natural deposit of gypsum found near Paris. This substance is a sulphate of calcium, containing two molecules of water in combination. When it is heated to between 300° and 400°, a considerable portion of this combined water is driven off and a friable mass results, which, when ground in suitable mills to a fine powder, forms the plaster of Paris of the trade. The "setting," or hardening, of burnt or calcined plaster of Paris is due to its disposition to reunite with the water of which it has been deprived. When mixed with water, the mass promptly combines with a sufficient portion thereof to make up for that which it has lost, and solidifies to a hard mass, having the composition of the original hydrated sulphate of calcium from which it was made. In undergoing this metamorphosis, the mass expands somewhat, and hence derives one of its most desirable properties for taking casts of objects, as it completely fills the mold and renders a very sharp impression. Care must be observed in burning the plaster not to over-heat it, as by this means a portion of the product becomes completely deprived of its combined water, and the resulting mass loses more or less completely its quality of setting with water.

CORRESPONDENCE.

[Letters are invited for this department on subjects related to the building interests. To secure insertion, all communications must be accompanied by the name and address of the author, not necessarily for publication. The publisher will not assume responsibility for the opinions of correspondents.]

Editor CANADIAN ARCHITECT AND BUILDER.

DEAR SIR,—I want to use metallic ceilings in two school buildings to be built in Deloraine and Melita, and would like to get the address of some Canadian dealer in this material, but see none in your paper. Can you give me the address of any one?

W. T. C. SHILLINGLAW,
Brandon, Man.

[The Metallic Roofing Co. and Messrs. Tucker & Dillon, Toronto, can supply you.—ED. C. A. & B.]

TORONTO ARCHITECTURAL CLUB.

Editor CANADIAN ARCHITECT AND BUILDER.

DEAR SIR,—At the last meeting of the Toronto Architectural Club, a motion to adjourn *sine die* was passed. This brings to a close for the present, at least, the work of this organization. Most of its older members, who were active in the preceding seasons, now devote their energies to the Ontario Association of Architects, while many of its younger members find their evenings fully occupied with the classes held at the Technical School. Thus it is that the attendance at the Club's meetings during the past year has been reduced to a very insignificant number. To many it may seem a pity that circumstances thus force the old Club to retire, but with such a small membership list, and the consequent small financial support, it is impossible to retain proper rooms, etc.

It is a pleasure to note that the Club retires honorably, having paid all its debts, and having a few dollars over, which have been voted to the O.A.A.

As one who has taken a great deal of interest in this Club, and who believes that members of our profession should do what they can to make their work as much a pleasure as possible, may I ask that the architects of Toronto take into their serious consideration the problem of providing suitable club rooms next winter for all classes of the profession, where magazines and papers may be found, and lectures, etc., may be held.

Yours truly,

ALFRED H. GREGG,
President T.A.C.

TENDERING FOR WORK.

Editor CANADIAN ARCHITECT AND BUILDER :

SIR,—Seeing you have started a department for correspondence in your paper, could you find room for these few lines on the present system of tendering for works, which is a subject of vast importance to the contractors of Canada ? It is almost an impossibility for contractors of reputation and ability to compete against the outsiders in the business, who give prices for work far below the actual cost, or the fair estimate of an architect. What is the result ?—the work, if completed, is done in a very defective manner, the architect suffers, the trade is given a bad name, and no one is satisfied.

I believe in fair competition between reliable firms, and although the architect should have "the right not to accept the lowest or any tender," yet it would be better for all parties if he would advise his client to refuse prices that are too low, as well as suggest the non-acceptance of figures that are too high. This may in some cases be a difficult matter, but I think architects could use their influence more in this direction than they sometimes do.

EQUITY.

MANUFACTURES AND MATERIALS

TERRA COTTA : ITS USE AND ABUSE.

Of late there has been a desire to discuss the merits and application of sundry materials in which manufacturers and artists have an interest. Concrete, iron and steel, plaster, and, lately, terracotta, have formed the staple of these discussions, for each of these has its champions and defenders as well as its detractors. Controversial meetings of this kind may not be the most practical or convincing means of promoting the use of any raw material or system, for advocates and producers are naturally prejudiced, while those who come to find fault are generally blind to every merit, as they seek to magnify every defect. We remember the time, however, when the advocates of iron and concrete were in a small minority, and had to bear the brunt of much more powerful opposition than they have now. Red brickwork and terracotta have passed through a similar obloquy and ridicule; and the friend of both materials can now smile on the complete reversal of fortune that has taken place.

With regard to the last named material, we have heard a good deal of late, and the manufacture of terracotta has formed the subject of a series of articles in the *Building News*. Of course like iron, and concrete and brickwork, it has had its opponents, who are generally uncompromising antagonists, able and willing to see nothing in favour of a material which is of a modern introduction, or reintroduction, and which has taken the place of stone to a large extent. Opposition of this kind does good in the long run, because it stimulates manufacturers and architects to make more strenuous efforts to disarm opponents. For example, one of the obstacles to the employment of terracotta has been difficulty in preventing the warping of the clay in drying and the shrinkage in burning. Now this obstacle has been practically removed by the process of manufacture described by Mr. S. H. Leech, of Messrs. Doulton's firm, in a paper read by him at the Institute on "Recent Developments in the Manufacture," and briefly reported in our last issue. The repeated complaints made by architects of "line" and distorted appearance of blocks used in cornices and string-courses, and other horizontal and vertical features like window jambs and pilasters, have to a large degree ceased, for producers of the material have, by increased care in preparing the clay, and in the process of drying and burning, been enabled to turn out blocks and pieces of terracotta of wonderful truthfulness and homogeneity of texture and colour. Another objection to the use of this material made by some architects is that from the nature of the manufacture it encourages repetition of details. Both of these objections no longer hold good. By the system of "direct working" carried out in the new process of manufacture by Messrs. Doulton, the clay is compressed into a state that can be finished in one operation—in fact, manipulated by hand. The block of clay is so nearly solid that it can be treated and finished much in the same manner as a block of stone; the blocks of cellular terracotta do not require to be filled up with concrete, and can be cut to any dimension and shape for fitting round iron stanchions for shafts or other purposes. Being amenable to hand, the compressed clay is capable of being directly worked by the artist instead of being subjected to a process of moulding which destroys all traces of the artists' touch.

These advantages of the "direct method" of working deserve recognition. As Mr. Ingress Bell pointed out in his thoughtful paper on this subject, we must divest our minds of the habit of thinking in stone, in dealing with this material, and until this habit is acquired our terracotta architecture will be a failure. One of the distinctions between working in stone and terracotta is that in the former material the mouldings and ornaments are produced by sinking the field. By a succession of sunken planes the mason produces his cornices, abaci, architraves; every moulding and ornament is sunk in the stone, even the enrichments and foliage of cornices and capitals in Classic as well as in Gothic work were roughly blocked out in the form of a rectangular or splayed projection in the stone, and then the carving was sunk below it. But this principle is not necessary in terracotta; the modeller can superlay and add on to the planes of the block, the moulding can be overlaid with ornament separately modelled, and, in fact, the whole feature can be built up in the clay or manipulated in any imaginable way; so that instead of sinking below the surface of the block to produce the moulding or ornament, the modeller can stick on his foliage or tracery. The effect to the eye of both systems is the same, but the process of production—one by sinking the field, and the other by overlaying it—is different, and seems to suggest that in terracotta, the designer, being less restricted by margins and planes, should have a different motive; in fact, his relief and ornamentation might be more often the *impasto* method. Certainly, stone forms of architecture are not those that should be copied; nor should we like to see revived a meaningless "rococo" style in clay. Both extremes should be avoided. No doubt Mr. Leonard Stokes' attack on terracotta derives much of its sting from the utter disregard of these principles rather than from any deeper cause. He sees rightly enough its abuse in the hands of men who have taken to it because it is fashionable, and cheaper than stone. That it can be called a "miserable mockery composed of mimic masonry" only proves the proposition we have advanced, and does not in the least damage the material in the eyes of the real artist with independent motives for doing better. Many objections can be urged against the application of this material. The concrete filling to terracotta blocks is no doubt open to the objection of sometimes causing fracture of the block by the inequality of the strains induced in the mass; for this reason the "cellular" plan is an advantage, because a greater substance can be given to the blocks. As a casing material for iron columns, fronts of shops, and the like, terracotta offers advantages over stone and even brickwork. Of course such an example as the church piers and arcade mentioned by Mr. Stokes, embedded in which iron stanchions are used with a girder over the tops of the arches to carry the clerestory, is an abuse of the material altogether. If small piers are required, why should not small solid blocks of terracotta be used like moulded bricks? and why should not the arches be solidly constructed in the same manner? But all the objections urged against it constructively and artistically are avoidable. The arguments against its durability, its colour, and its dreariness apply with more force against many kinds of stone which become dull and monotonous in the extreme. Can we look with any satisfaction on the black and furred appearance of many of our London smoke-begrimmed facades? —*The Building News.*

Mr. W. B. Malcolm is enlarging his business premises on Church street, Toronto, and is fitting up new offices and show rooms.

The Standard Drain Pipe Co., of St. Johns, Que., are sending out an attractively printed illustrated price list of their products.

A company with a capital stock of $250,000 is being formed to take over the business of Messrs. C. B. Wright & Sons, cement manufacturers, at Hull, Que.

The Toronto Vitrified Paving Brick and Stone Company, is being organized at Toronto with a capital stock of $500,000. Mr. R. W. Prittie is provisional director.

Messrs. Lefebore & Nelson are exhibiting in the Imperial Building, St. James street, Montreal, a display of metallic ore blocks used for facing old or new buildings. It is proposed to establish large works for the manufacture of these goods.

The Toronto and Orillia Stone Co., Ltd., has lately been organized. The Company own a limestone quarry 45 acres in extent at Longford, Ont. The officers of the Company are: President, Andrew Tait, Orillia; vice-president, Jos. Tait, M.P.P., Toronto; secretary, E. C. Wainwright, Orillia.

The Dominion Sanitary Pottery Company, of St. Johns, P.Q., is forwarding to the Chicago Exposition, sixty handsome specimens of closets, their own manufacture. The Artistic Decorating Co., of St. Johns, executed the decorations, which are most elaborate. The make and finish of the goods will compare well with the products of the great potteries of other countries.

Major Trotter, of the Standard Drain Pipe Co., has invented an ingenious contrivance for saving coal in potteries. The heat of one kiln, after passing through the pipes, instead of going to waste, is made to go through a second and third kiln. By this means three kilns are fired at the cost of two, or a saving of one-third of the amount of fuel used in the present system. The invention is to be patented in Canada and the United States.

The Fuller & Warren Company's system of heating and ventilation, which is in extensive use in the United States, is now being introduced into Canada by the Robb Engineering Co., of Amherst, Nova Scotia, having been installed during the past few months in new school buildings in three towns in Nova Scotia: Amherst, Yarmouth and Wolfville. It speaks very highly for this system that it is in use in a large number of the best schools in Massachusetts, where legal enactments have made it imperative to comply with the highest attainable sanitation.

We regret to have to announce that the manufacturing department of the St. Johns Stone Chinaware Company's works at St. Johns, Que., was destroyed by fire on the 4th of March. The proprietors had recently completed extensive improvements, including new machinery costing $25,000. Their loss is placed at $100,000, against which there is insurance to the amount of $54,000. The works gave employment to 225 persons. The company will at once put into operation the Dakin pottery recently acquired by them, and it is expected will proceed as soon as possible to rebuild and re-furnish the works which have been destroyed.

Messrs. Richardson, Walker & Co., of Portland, Maine, who are extensive wholesale and retail dealers in southern pitch pine and cypress timber and lumber, write us that they have lately shipped some large orders into Canada, and believe that there will soon be a large demand in this country for southern woods. Cypress approaches most nearly in quality to white pine, which is becoming increasingly scarce, and is claimed to be in some respects superior to the latter, as being firmer, less subject to contraction and expansion, capable of better finish, proof against insects, etc. Messrs. Richardson, Walker & Co. through our advertisement pages invite correspondence from Canadian architects, engineers, builders, etc.

Many architects and builders consider that Longleaf pine that has been bled and tapped for turpentine suffers in strength by virtue of same and they restrict the use of it in construction, but by recent tests made by the forestry department at Washington, it has been proved that the timber does not suffer from such tappings. On the contrary it exhibited if anything greater strength, which may be accounted for by the fact that turpentine orchards are located mostly on sites which produce better quality timber and larger yields of turpentine. The reasons of the wood not suffering from these operations is because the older resins of the heartwood being non-fluid, the turpentine flow is confined to the sap wood. No difference is discernible in the appearance of tapped and untapped trees, and in spite of specifications calling for unbled timber of this kind, such wood is often pparded without being discovered.

SHAVINGS.

The Dominion Government have granted the sum of $1,000 towards a national art gallery.

Mr. G. Wilson, builder of St. Catherines, is using electric power for operating the machinery of his works.

Good material for making sewer pipes can be found at Weston. There is also a material in the neighborhood suitable for painting purposes.

Mr. E. Colonna, of Montreal, has been awarded the prize of $100 offered by the Architectural League of New York for the best design of a loving cup.

Mr. R. Forsyth, of Montreal, has entered an action against the Canadian Granite Co. to recover royalty on granolithic pavement used by them, and asks for an injunction on the execution of more contracts.

Mr. Hunt, an American architect, has been awarded the gold medal given annually by the Queen through the Royal Institute of British Architects.

The first meeting of the Hamilton Sanitary Association was held recently in the Board of Trade building of that city under the presidency of Mr. A. G. Ramsey. An account of the working of the Montreal Sanitary Association was given by Mr. W. Hopkins, and a committee composed of Messrs. A. G. Ramsey, Adam Brown, A. Turner, Major McLaren, G. Roach and D. Rennie was appointed to nominate a council. Evidence of the interest being taken in the Association was shown by the large number of citizens at the meeting.

An organization has been formed in Canada to regulate the trade and maintain a uniform scale of prices in the building paper line. At a recent meeting the following scale of prices was adopted: Tram straw board, 60 cents per roll; Tarred straw board, 70 cents per roll; Fibre paper not less than above prices; O. K. or I X L. paper, 70 cents per roll; Tarred felt, $30 per ton. Terms —Four months, 3 per cent. off cash 30 days. Mr. E. G. Burke, of Campbellford, is president of the association, W. T. Miller, of Trenton, vice president, and C. T. Williams, of the firm of George W. Reid, secretary.

An asphaltic-concrete material for floors is described in "Indian Engineering," under the name of "bastard asphalt flooring." It consists of a 6-in. layer of 1-in. broken stone boiled in tar, with an upper ½-in. layer of coarse gravel or small stone chips, and slaked lime (2 parts of the former to 1 part of the latter), boiled in a mixture of coal tar and pitch. Both layers to be rolled, and the upper one finished with a top dressing of sand ¼ in. thick, and again rolled. This description of flooring has been used for freight shed platforms, etc., and found to be durable and satisfactory when not exposed to the sun. For the floors of ordinary buildings a thickness of 3 ins. is sufficient. The tar must be well boiled.

The loss of property from fire during 1892, in Toronto, amounted to $210,115, while in Montreal, which is not much larger than this city, the damage amounted to $775,000.

The Woodstock Court House Committee have settled the differences with their contractor, Mr. Brown. The account was reduced from $16,400 to $13,300, which amount was accepted in settlement.

A new coat of arms for the Berlin court house weighing over 300 pounds recently arrived from England, where it was made.

Mr. C. F. Mitchell, of 168 Borden street, Toronto, has entered an action against the trustees of the College street Presbyterian church to recover $683.71 a balance alleged to be due to him under his contract for the erection of a school room for the church.

Unglazed Fire Clay, Flue Lining, Sewer Bottoms or Invert Blocks, Stable Paving, Bricks and Tiles, *English and Scotch Sandstone*, Glazed and Enamelled Bricks and Tiles for internal lining of baths and walls, English Art Tiles, Floor Tiles, Sanitary Earthenware etc. Special quotations for Cupola Kilns, Retorts and Blocks.

NOTE.—Only pure, SCOTCH, unglazed Fire Clay Linings will be kept instock—any other quality is worthless for resisting heat. Correspondence invited. Quotations promptly furnished.

Office: 31 WELLINGTON STREET, MONTREAL.

USEFUL HINTS.

PITCH pine beams will shrink in thickness from 18¾ inches to 18¼ ; spruce, from 8½ to 8¼ ; white pine, from 12 inches to 11⅞ ; yellow pine, a trifle less. Cedar beams will shrink from a width of 14 inches to 13¼ ; elm, from 11 to 10¾, and oak from 12 to 11⅜ inches.

GLASS FROSTING.—Dissolve Rochelle salts in gum-arabic water ; let it stand over night, and after cleaning off the glass well, flow the solution on so that it will not run ; lay the glass flat, if convenient, and when it commences to set take a pointed stick and dot it in rows to suit the taste ; put the dots about 1½ inches apart. If you wish it colored use anilines—red, blue or green and gamboge for yellow or gold color, then flow on a thin coat of damar varnish, and it is finished.

NAMES OF NEW COLORS.—"Angelique" is a pale apple green. "Beige," really a beige drab. "Caster," a dark beige. "Castile," a bright buff yellow. "Coquelicot," a bright brick red. "Diavolo," a bright cinnamon. "Emeralde," a brilliant emerald green. "Floxine," a brilliant light crimson. "Geranium," a pale geranium red. "Mascot," a medium moss green. "Murier," an indefinite moss green. "Paradise," a bird of paradise yellow. "Bivoine," a deep metallic scarlet. "Vareche," a dark moss green.

A GOOD CEMENT.—Dissolve 8 ounces of sugar in 24 ounces of water in a glass flask on a water bath, and to the thin syrup add 2 ounces of slacked lime, keep the mixture at a temperature of about 160° to 165° Fah. for three days, shaking frequently ; then cool, and decant the clear liquor. Dilute 6½ ounces of this liquor with as much water, and in the mixture steep 16 ounces of fine gelatine for three hours after heating to effect solution. Finally add to the mixture 1½ ounces of glacial acetic acid and 15 grains of pure carbolic acid.

ELECTRIC push buttons should be clearly visible on the front door, and the more conspicuous they can be made without offending good taste the better. The practice of placing such push buttons in some obscure place, hidden in the shadows of the moulding of the door jamb, where they can neither be seen nor found in the dark, is a poor one, causing much annoyance which might easily be avoided. The first purpose of a push button is to be useful and this purpose is best served when it is plainly visible and accessible to those desiring to enter the house.—*Southern Architect.*

CREDIT VALLEY BROWN STONE

From Carroll & Vick's No. 6 Quarry, Credit Forks, Ont.

SANDSTONE, fine grained, reddish brown. Contains quartz, and a little felspar and mica. The stone is in beds of four feet and under, and can be handled in pieces up to five tons. Quarry 300 yards from Railway.

Specimen.	Section under Pressure	Height.	Crushing Load.	Crushing Stress per sq. in.	Average Crushing Stress per Square Inch
	Ins.	Ins.	Pds.	Pds.	Pds.
A	.....	.....	.....	.....	
B	2¾ × 3	2⅞	131,000	15,188	
C	2⅛ × 3	2⅞	130,000	14,751	
D	3 × 3	2⅞	133,000	14,777	14,905

14,905 pounds is the average crushing strength per square inch of our Credit Valley Brown Stone.

The highest standard of test attained by any pure Sandstone in America.

IN confirmation of the facts above stated, we have pleasure in directing your attention to the accompanying table, showing the result of the test of our stone, in connection with the series of tests of building stones conducted in 1892 at the School of Practical Science, Toronto, under the direction of a committee of the Ontario Association of Architects.

By referring to the results of the tests above mentioned, it will be seen that the average crushing stress of the majority of Canadian and American sandstones is far below that of ours, the difference in our favor ranging from 75 to 50 per cent.

The Credit Valley Brown Stone, owing to its modest tone, harmonizes beautifully with red or cream colored brick.

It has been reported that there is difficulty in obtaining Credit Valley Brown Stone. To correct this mistaken notion, we wish to state to architects and the public that we have 40,000 cubic feet of stone ready to ship on the shortest notice, which can be followed up with an unlimited supply. Last year we made extensive additions to our plant and opened up new quarries and mines, and will supply promptly all orders given to us or our agents.

In a recent letter to the city in reference to the court house question, Messrs. Neelon & Co.'s solicitors state that labor and materials are very perceptibly lower at the present time than they were in 1888. This is incorrect, in fact the movement is the other way. Stone-cutters who received 38 cents per hour in that year are now getting the high wage of 43 cents, and bricklayers now receive 35 against 33½ cents per hour in 1888. The material market also shows some prices to have risen, and stone, the material more particularly referred to, is 20 per cent. dearer than at that time.

WE had the pleasure of presenting to our readers some months since a brief paper on "The Doorway," originally presented by Mr. Gemmell for the consideration of the members of the Toronto Architectural Guild. It was intended to serve as the introduction to a series of brief papers by members of the Guild on the subject of house design. It will be a matter of regret to our readers to be informed that the further consideration by the Guild of this interesting subject was conducted orally, and the results are consequently in a measure lost.

THERE is room for much improvement in the efficiency of electric door bells as in many instances they are fitted up. It is not an infrequent thing to see posted above the push button beside a residence door, the intimation: "Bell out of order; please knock!" It sometimes happens, as in the case of a prominent Toronto merchant, recently, that considerable time elapses before the inmates of the house become aware that the door bell is failing to discharge its duty. The merchant's friends in vain had been pushing the button for a week or more. When at last the discovery was made that the bell was not working, the owner went down town and expended $3.50 in repairs. What was his regret at having done so when the first person to demand admittance after the bell had been put in order was a policeman bearing a warrant summoning him to the police court to show cause why he had not removed the snow from the sidewalk in front of his premises.

THE Ministers of Finance and Customs are at present receiving deputations representing the various important manufacturing and commercial interests of the country for the purpose of learning what readjustment of the existing tariff is required. The present may therefore not be an inopportune time to mention that architects have reasonable ground for complaint in this connection. Few if any of their supplies are or ever will be manufactured in Canada. Even the United States has thus far been able to produce only the cheaper grades of drawing paper and instruments. In view of these conditions, the duty of 25 to 35 per cent. imposed upon these materials when imported into this country from Europe must be considered unnecessarily burdensome. It might very properly be reduced by at least 50 per cent. Canadian architects at present find themselves in the unfortunate position of being highly taxed on everything they require to use, while virtually the tariff does not protect them from the competition of foreign architects.

In the construction of elevator shafts and the fitting up of elevators, architects would do well to see that a space of five to seven feet at least is provided between the top of the elevator when it reaches its highest point of travel and the roof of the shaft. The necessity for such a requirement was brought to our attention by an accident which happened recently. The automatic regulating device connected with an electric elevator failed to operate when the current was turned on, and the car shot up the shaft. Fortunately it was empty, and more fortunately still, two attendants who a moment before were on the top of the car for the purpose of oiling the slides, had made their exit from the shaft. If the accident had occurred one minute earlier these men must have been crushed to death at the top of the shaft, as the stopping point of the car is only two or three feet below the roof. This is not the first occurrence of the kind that has come to our notice. In addition to the necessary provision above mentioned, the safety of passengers demands that the controlling devices be made more effective.

THE York Pioneers have taken in hand the erection of a monument to Governor Simcoe, and the Ontario Government will be asked to grant a suitable site for the same in Queen's Park, Toronto. It is very desirable that the memory of the man who founded the Queen City of Canada and caused it to be made the seat of legislation for Ontario, should be perpetuated in the manner proposed. The time also is most appropriate, as the present month marks the centennial of the founding of the city. If a suitable site be granted, as we have no doubt will be the case, the York Pioneers will make every effort to erect a statue which shall be recognized as a work of art, and a deserving memorial of one of the greatest pioneers of Canadian civilization.

AN international congress of architects is to be held in Chicago under the auspices of the World's Congress Auxiliary, during the week commencing July 31st. The object is stated to be to bring together the eminent architects of all countries for friendly intercourse, comparison of methods and results, and the promotion of their mutual interests in the profession. The following subjects have been selected for consideration at this congress:—Workingmen's Houses; Modern Department Houses; Ancient Department Houses; Laundries in Houses, Health Effect; Modern Stables, large and small; Responsibility of Architects in Constructional Matters; Responsibility of Architects as to Plans; Responsibility of Architects in Decorative Matters; Sculpture and Architecture; Painting and Architecture; The Client's Right to Service, as to Drawings; Ownership of Same, Specifications and Details, as to Supervision, etc.; Mechanical Engineering in Architecture, and the Architect's Responsibility Therefor; Modern Steel Construction; Fire-Proofing of Buildings to Date.

THE public works department at Ottawa are evidently anxious to protect themselves from a class of undesirable contractors, and in order to do this have issued new regulations regarding Government contracts. In future the deposited cheque is to be to instead of 5 per cent. on the amount of contract, and only 80 in place of 90 per cent. will be paid on progress estimates. This new arrangement may be the means of keeping smaller contractors from competing for the work, but if a contractor has the confidence of his employer there is no reason why restrictions of any large amount should be placed on his progress certificates. During the erection of the Ontario Parliament Buildings payments on account to the contractors were made to the amount of 90 per cent. on the value of the work executed, and the work financially has been carried out in a satisfactory manner. Larger amounts than 20 per cent. are often kept back by architects upon progress certificates, but it has often been the means of retarding the progress of works even in the hands of honest contractors.

WE had occasion recently to refer to the unfair treatment accorded by the Toronto city council to Mr. Alex. Gartshore, of Hamilton, whose tender for water pipe, being the lowest, was rejected in favor of a higher tender by a local firm. The sequel to this piece of injustice now appears in Mr. Gartshore's refusal to again submit a tender for material required by the city of Toronto when invited to do so. In consequence of this refusal only a single tender was received. It is a short-sighted policy for corporations to exclude the competition of outside contractors. By doing so they are compelled to pay higher prices for work and material, and as gradually the impression gets abroad that no outsider need apply, the local contractors are enabled to combine and have things all their own way. In the case to which we have refered, however, outside contractors were led to submit tenders on invitation of the Board of Works in the belief that the Council would deal with the same impartially and on their merits. Their confidence in this regard having been disappointed, as honorable men they very properly refuse to again be made dupes of.

IT was not without a feeling of regret that we read the letter of Mr. Gregg, in our last issue, announcing the dissolution of the Toronto Architectural Club, formerly the Toronto Architectural Sketch Club. This regret will be shared by many of our readers who have themselves been benefited by connection with the Club, or who are familiar with the work it achieved. The many valuable papers read by specialists on various subjects at the Club meetings during the last four or five years, were instructive not only to the members, but also through their subsequent publication in these columns, to a large constituency outside. Several competitions took place each season with results which were creditable to those taking part and highly beneficial to students and others both in and out of the Club's membership. It is most desirable that the good work of this organization should by some means be perpetuated. The existence of several local associations with objects more or less common, no doubt proved a source of weakness to all. From the elements of these organizations it should now be possible to form, as Mr. Gregg suggests, a new one which would secure a large membership and be efficient in promoting the interests of architecture and of architects both young and old in the city of Toronto.

THE appropriation of $60,000 passed by the Legislature of British Columbia for the erection of new Government buildings at Victoria, is meeting with vigorous opposition from the residents on the mainland. The Governor-General-in-Council has been memoralized to disallow the act of the Legislature. The area of the mainland portion of British Columbia is 366,300 square miles and the population 61,406, as compared with an area of 16,002 square miles and a popultion of 36,767 on the island of Vancouver. This is given as a reason why the proposed expenditure on new Parliament buildings should rather be applied to public improvements on the mainland. Another argument in support of this contention is that the people of the mainland contribute over two-thirds of the provincial revenue. It is further urged that the estimated yearly expenditure of the province will exceed the total revenue by about $200,000, and that therefore the revenue cannot sustain the charge which the proposed expenditure would entail. There is likewise the contention that the capital of the province should be removed to the mainland on account of the majority of the of the population being resident there, and because of the inconvenience and expense imposed upon those who have to transact business with the Government at Victoria. The residents of the mainland recognize in the proposal to erect new buildings at Victoria a determination to fix the seat of Government there, hence the opposition which is being manifested. It is by no means likely that the authorities at Ottawa will disallow the act of the provincial legislature, therefore the only way in which the erection of the proposed new buildings is likely to be prevented is by the defeat of the existing government at the polls. Meanwhile preparations are actively going forward for the commencement of building operations.

THE London *Lancet* of the 8th of April contains the result of a very thorough enquiry concerning the water supply and general sanitary condition of the city of Chicago. This enquiry, the *Lancet* states, was undertaken by members of its staff for the benefit of Europeans who may visit the World's Fair. As proportionately a larger number of Canadians than Europeans are likely to visit Chicago during the next six months, the result of this enquiry may very properly be stated for their benefit. The Chicago river is declared to be in a "disgusting condition," especially in the vicinity of the stockyards, not far from the Southern Branch Pumping Station, where the filthy conditions are said to be such as to defy description. This condition is induced by animal refuse, indiscriminately mixed with sewage, being dumped into the river, in consequence of which the air of the locality is alleged to be charged with nauseating odors which cannot but be highly injurious to health. The domestic supply of water, which is drawn from Lake Michigan, is found to be in respect of color, total solid matter, hardness, chlorine and oxygen required to oxidize organic matter, superior to the choicest of London's supply. It contains, however, low forms of vegetable life and matter in suspension. The probability of these finding their way through the mains is such that visitors are counselled to use nothing but boiled or filtered water. Another source of danger is shown to exist in the custom of using ice in drinking water. A sample of water which had passed through a filter, upon being analyzed was found to contain low forms of vegetable life due to the melting therein of impure ice subsequent to filtration. Thus by the use of ice the good effects of filtration are nullified. In the light of the result of the above enquiry Canadian visitors to Chicago should keep as far as possible away from the neighborhood of the Chicago river, should insist upon the water they drink being boiled or filtered, and should avoid the use of ice.

THE safe resistance of floors in public buildings and other places where dense crowds are likely to congregate is a question of vital importance. From recent experiments it would appear that architects do not work on safe calculations regarding this matter. It is generally understood that a crowd of people when densely packed together cannot impose more weight than ninety pounds per square foot. The tests referred to, however, show that the dead load should far exceed that amount. Mr. C. H. C. Wright, lecturer in architecture at the School of Science, Toronto, in some experiments last March with thirty-two of his students, found that when they were placed close together in an area of 33:46 square feet, there was a load of 139 lbs. to the square foot. Their aggregate weight was 4,656 lbs., which shows the average weight to be 145.5 lbs. Mr. Bindon B. Stoney, the distinguished authority on bridges and roofs, has also conducted two experiments along this line. He packed a crowd of fifty-six laborers on the deck house of a ship, giving a total weight of 8,404 lbs., or an average of 145 lbs. As the area covered was 57 square feet, each man had a little less than one square foot of standing room, and gave a load of 147.4 lbs. per square foot. On another occasion he collected 73 laborers on the floor of a hut having an area of 77 square feet. Their aggregate weight was 10,948 lbs., an average weight of 150 lbs. to each. The result gave 142 lbs. to each square foot, and there was a possibility that two or three more men could have been squeezed in. Professor Kernot, of Victoria, tried a similar test with his class of engineering students. He packed 16 of them weighing 2,455 lbs., within an area of 18 square feet, which shows an average of 153.4 lbs. to each man. The weight per unit of area was therefore 134.7, and there still remained unoccupied space. From these figures it would appear that the resistance of floors which are likely to carry heavy weights should not be less than three hundred pounds to the square foot, for as the average dead weight comes close upon 150 lbs. per square foot, double that strain should be allowed as a provision against sudden movements in a crowd, as in the case of a panic.

THE condition of the sanitary arrangements in the buildings of our towns and cities is of the utmost importance at the present time in view of the threatened cholera epidemic. It is therefore pleasing to note that Montreal and Hamilton are taking special steps to have such appliances in their respective cities as complete and sound as possible. This example should be followed by sanitary authorities in other places. It is most essential that plumbing work should be perfectly executed, as the least defect reveals itself by its unpleasant and unhealthy consequences. One of the chief requirements which very often does not receive sufficient attention, is the ventilation of the work in order to prevent any foul air being water-bound. There should always be a free escape provided for the air displaced by flushing, which otherwise would bubble up through the water by which it is supposed to be hermetically confined. Every soil pipe should have a ventilating pipe from the top carried above the eaves to the roof of the building, by which means all foul vapours escape to the open air. In places where the electric cars are in operation, there is another strong reason why a general inspection of plumbing work should be made; this is the discovery of electrolysis to metals caused by earth currents of electricity. In Hamilton, for instance, seven service pipes in the vicinity of the street railway power house were found to have been eaten out from this cause. The chemical decomposition to metals from electricity in the way mentioned is a serious matter, and one which should have the attention of everyone interested in the sanitary welfare of towns and cities.

WHILE minor matters are engaging the attention of the mayor and aldermen of the city of Toronto, the all-important subject of a pure water supply and an improved method of sewage disposal, are apparently receiving but scant consideration. There seems to exist no determination in the mind of the Council to grapple with the problem and stay with it until its proper solution shall have been discovered and carried out. Theories, reasonable and unreasonable, are from time to time advanced, but nothing is done. We are told that the effort to conduct the pure water of the lake through the sewage laden waters of the bay to the pumping station and thence through the city mains to the homes of the citizens, is contrary to common sense and will never succeed. This may in a measure be true. We would like to point out, however, that the chance of obtaining a pure supply of water by the present means would be vastly increased if an intercepting sewer were constructed which would carry the city sewage along the esplanade to a point where it could be safely discharged into the lake. After the bay had thus ceased to be the receptacle for filth from the city sewers, it might be cleansed of the deposits which at present it contains, and the water rendered comparatively pure by continual contact with the water of the lake, for the bringing in of which means could easily be devised. Such a method of procedure would be going to the root of the difficulty instead of trying to find means to mitigate its effects, while the cause is allowed to remain undisturbed. It may be a very good thing to know that by the application of chemicals the germ-laden deposits of sewage in the slips at which the pleasure boats of Toronto embark and disembark their passengers can be rendered less dangerous, but it would be much more satisfactory to know that the deposits did not exist. Toronto certainly is in need of public parks, to the securing of which the attention of the Mayor has lately been directed, but infinitely greater is the need of a pure water supply and a trunk sewer for the proper disposal of the sewage of the city, both of which we commend to his prompt and most serious attention.

THE second session of the Toronto Technical School has recently closed. It is a pleasure to learn that the results of the two sessions have greatly exceeded the anticipations of the promoters of the movement. During the session which has just closed the students numbered about three hundred. The attendance of this large number of students is said to have been regular and their progress most satisfactory. In view of the eagerness which has been displayed in taking advantage of the facilities offered for the acquirement of instruction in the various departments of knowledge required by artizans, we may look forward with confidence to the continued growth and increased usefulness of this new department of education. Indeed we shall not be surprised to see at no distant day technical instruction and manual training made a part of our system of public instruction. Such a movement has already taken place in some American cities, notably St. Paul, Minn., where there are in operation what are known as manual training high schools. The value of these schools is regarded as such that when recently the proposal was made to abolish them on the ground of expense, the Chamber of Commerce in a report on the subject said: "Destroy all the schools if you must, but leave us the manual training high schools." The fact is apparent that our educational system does not as it should attempt to instruct the pupil in those subjects which are likely to be of most advantage to him in his future life. Notwithstanding that one pupil is foreordained by circumstances to earn his living by means of his hands and another by means of his head, our public school system assigns to each exactly the same studies. This is manifestly wrong, and the effect may be seen in the dislike which many youths manifest to forms of employment in which skilled hand labor is required. It may likewise be observed in the overcrowded ranks of the professions and what are known as genteel employments. What is needed to ensure a higher average of comfort among all classes and a higher condition of prosperity for the country is an increase of properly trained agricultural and artizan producers.

DURING the last five years architects, reputable builders and supply merchants have alike suffered from the doings of irresponsible and incompetent contractors. How to get rid of this undesirable class is problem to some extent an unsolved, although the quiet condition of the building market during the past year has been the means of breaking up many so-called "firms" whose members have returned to the ranks of journeymen, which they should never have left, or have sought pastures new in other lands. Some of the labor unions, especially the bricklayers, have also to a certain extent prevented by their by-laws a continuance of a competition farce. As far as the merchants are concerned, they are to a large extent responsible for their own loss; so long as they are willing to supply such customers with materials, so long may it be expected that they will continue to build at other people's expense. We are pleased to observe that merchants are learning by sad experience that this class of trade is better left alone. The trade in Chicago have originated a plan which to a large extent will eliminate these difficulties, and which is worthy of the consideration of Canadian contractors and supply firms. A mercantile agency has been incorporated by which reliable members, contractors and merchants, are protected. This agency keeps a perfect record of the financial responsibility of every building contractor in Chicago, compiled from opinions received from every person who has had business transactions with him. Stockholders alone are allowed to use this information, and they must be manufacturers of builders' supplies, approved of by a board of directors comprised of seven men appointed from the different interested industries. The collection department is a special feature of the concern. Parties temporarily embarrassed have every opportunity, afforded them to make favorable settlement, while legal means are used to make those pay who are able but will not. There is also a system of arbitration in connection with the agency for the adjustment of disputed accounts. Should this scheme work out in practice as well as it looks in theory, contractors and material merchants in Canada would do well to take some steps along this line not only to improve their present condition but to prevent the disreputable contractors forced out of Chicago by the means described from coming into Canada.

IN another column we refer to the proposed act to protect the rights of wage earners as introduced by Sir Oliver Mowat in the Ontario Legislature. We also give a report of the visit of the deputation from the Builders' Exchange of Toronto to the Government asking for amendments to the bill. Should this bill become law without some modification, a great obstacle will be placed in the way of the building trade of Ontario. The object of the act itself is good, for journeymen have occasionally suffered from loss of their wages through dishonest and speculative builders, but if the third section of the act be passed as it now stands, the proposed remedy would be the means of crippling the operations of contractors to a large extent. It is also a question whether the section would reach those for whom it is intended. Taking the contractors as a body, we cannot help thinking there is only a small minority who would willingly keep any of their journeymen from what is justly due to them for wages. Therefore it is not reasonable to place such severe obligations upon the whole body of contractors with a view of overcoming the possible wrong-doing of the few. The President of the Toronto Builders' Exchange stated, when before the Government, that during the existence of that institution he had not heard of any of its members being guilty of such unjust action. As the membership of the Exchange contains most of the building contractors of any note in the city this statement should be regarded as a strong argument against unnecessary restrictions. The other clauses in the act do not propose any radical change in the existing Lien Act, but one cannot understand why a contractor should be required to produce his receipted pay list, as well as make a declaration stating that all wages have been paid to date, when applying for a progress certificate, while a mortgagor who is often himself the builder need only make the declaration referred to, when asking the mortgagee for an advance. It would appear from this, that the veracity of the contractor, working under ordinary progress certificates, is not considered by the promoters of the bill to be as reliable as that of builders who find it necessary to mortage their land before commencing to build. We think also that sub-contractors should come under all the provisions of the bill, for if the principal contractor is held respon-

sible for all payments to the journeymen on a building, he should have some protection against any contractors to whom it is necessary to sub-let part of the work. The members of the Government, who heard the delegation, promised that the objections raised by the delegation to the measure in its present form would have their best consideration, and from the remarks that fell from them during the interview there is reason to believe that the bill will be modified in the direction of their wishes.

design and of the block plan, showing the grouping. A description of the design, as published in the Victoria *Colonist*, appeared in the CANADIAN ARCHITECT AND BUILDER for April. The site is an extremely beautiful one, well laid out with trees and grass and with James Bay in the foreground divided only from the grounds by a road.

ONTARIO ASSOCIATION OF ARCHITECTS.

A MEETING of the Council was held on May 2nd to consider the report of the Board of Examiners upon the recent examinations of the Association. The following are the returns:

FINAL EXAMINATION.

Passed—S. G. Beckett, Wm. Fingland. Conditioned—T. A. Harvey; Wm. Rae.

SECOND INTERMEDIATE EXAMINATION.

Passed—W. F. Howland, W. A. D. Graham, W. P. Over. Conditioned—C. J. Read.

FIRST INTERMEDIATE EXAMINATION.

Passed—A. Baker, J. P. MacLaren. Conditioned—F. W. Langley.

Candidates who are conditioned will be allowed to take a supplemental examination in the subjects in which they have failed. This examination will be held in the autumn. When the date is fixed notice of it will be sent to each candidate entitled to come up for the examination.

CUT VERSUS WIRE NAILS.

There are over three hundred varieties of nails in existence, deriving their names chiefly from the shape of their heads and points, or according to the purpose for which they are generally used. Two of the classes in most common use are those known as cut nails and wire nails. The former are cut by machinery out of sheets of iron and have their angles sharp but rough; the latter are known also as French nails (a pointes de Paris) are round, very tough, and are supposed to possess the good quality of not splitting the wood when properly used. In some recent experiments in the United States to ascertain the relative holding powers of these two classes of nails some interesting facts were developed. In the 58 series of tests, comprising ten pairs of cut and wire nails, of one size and weight, driven into spruce wood, 7160 nails were used, varying in length from 1⅛ to 6 inches, and in each case the cut nails showed superior holding power. An analysis of the several tests is as follows:

In spruce wood in 9 series of tests, comprising 9 sizes of common nails (longest 6 inches, shortest 1⅛ in.) the cut nails showed an average superiority of 47.51 per cent.

In spruce wood in 6 series of tests, comprising six sizes of light common nails (longest 6 inches, shortest 1⅛ in.) the cut nails showed an average superiority of 47.40 per cent.

In spruce wood, in 16 series of tests, comprising 15 sizes of finishing nails (longest 4 inches, shortest 1⅛ in.) the cut nails showed an average superiority of 72.22 per cent.

In spruce wood, in six series of tests, comprising 6 sizes of box nails (longest 4 inches, shortest 1¼ in.) the cut nails showed an average superiority of 50.88 per cent.

In spruce wood, in 4 series of tests, comprising 4 sizes of floor nails (longest 4 inches, shortest 2 in.) the cut nails showed an average superiority of 80.03 per cent.

In spruce wood, in above 40 series of tests, comprising 40 sizes of nails (longest 6 inches, shortest 1⅛ in.) the cut nails showed an average superiority of 60.50 per cent.

VALUE OF ADVERTISEMENTS.

WE have no patience with those mistaken minded members of the architectural profession who look at the advertising pages of their periodicals as useless, burdensome material, to be torn off without a second thought and consigned to the waste basket. These men are always behind the times, opinionated to the last degree, and lacking that knowledge of improvements in building materials and appliances which they owe to their clients. They do not realize that through the advertising columns of the professional journals there is set forth the record up to date of the inventions and discoveries that are enabling us to build better, more quickly, more cheaply. The manufacturer, introducing a new form of building material, or some patented appliance, seeks to reach the architects through what seems to him the most natural, the most legitimate channels,—the advertising columns of the architectural press.—*The Brickbuilder.*

CORRESPONDENCE.

[Letters are invited for this department on subjects related to the building interests. To secure insertion, all communications must be accompanied by the name and address of the author, not necessarily for publication. The publisher will not assume responsibility for the opinions of correspondents.]

COPYRIGHT OF PLANS.

Editor CANADIAN ARCHITECT AND BUILDER. May 5th, 1893.

SIR: Re the complaint of piracy practised by parties claiming to be architects, in the April number of the CANADIAN ARCHITECT AND BUILDER, permit me to say that in the United States a copyright can be obtained for a design, map, drawing, etc. This, however, must be done before publication of the article. Two complete copies of the work must be sent prepaid, or under the free labels furnished by the librarian, to perfect the copyright. Without the copies above required, the copyright is void, and a penalty is incurred. No copyright is valid unless notice is given by inserting in each copy, "Entered according to Act of Congress, in the year —— by ——— in the office of the Librarian of Congress at Washington."

The copyright secures the exclusive right of publishing the article copyrighted for the term of 28 years. Is not this the practice in Canada? Then why can't those who feel injured by the piracy of so-called architects, as you call them, get redress?

Respectfully,

VOX POPULI.

A CONTRADICTION.

OTTAWA, April 24th, 1893.

Editor CANADIAN ARCHITECT AND BUILDER.

DEAR SIR: In your April number we find a paragraph stating that Mr. Forsyth, of Montreal, has entered suit against us "to recover royalty on granolithic pavement," and that he "asks for an injunction on the execution of our contracts.'

These statements are absolutely untrue. Mr. Forsyth has not entered an action against this Company for the above or any other cause.

Yours truly,

CANADIAN GRANITE CO. (LTD.),
Per A. MacLean, Pres.

[The paragraph in question was based upon uncontradicted statements which appeared in the daily press, and was published in good faith. In view of the above contradiction, however, we desire to express our regret that it should have appeared in this journal.]

COMPETITIONS.

Competitive designs for a new City Hall for the City of New York are invited by the City Board of Commissioners until the first of September. Printed instructions regarding this competition may be obtained on application to the Comptroller, 280 Broadway, New York city.

The competition for designs for a memorial monument to the late Sir John A. Macdonald, to be erected in Toronto, has been decided in favor of Mr. Hamilton McCarthy, of Toronto, Mr. P. Heber and Mr. J. Dunbar, respectively. The statue will cost $10,000.

PERSONAL.

The death is announced at Adolphustown, Ont., on April 19th, of Mr. Thos. Gibbs, one of the oldest provincial land surveyors of Ontario.

Mr. S. G. Curry, ex-president of the A. O. A., has of late been temporarily residing at Port Hope, Ont., where he has several commissions to execute.

Mr. T. A. Morrison, of Montreal, lately spent a couple of weeks in Toronto and the west, in behalf of the business interests with which he is identified.

Mr. J. R. Rhind, and Mr. Edward Maxwell, architects, Montreal, have removed their offices to the new Board of Trade Building. Mr. H. Austin Jones, architect, of the same city has removed to No. 204 St. James street. Messrs. Cox & Amos, architects, have removed to Temple Building.

Mr. J. C. A. Heriot has entered the office of Mr. A. F. Dunlop, R. C. A. architect, Montreal, as junior partner. Mr. Heriot was a former pupil of Mr. Dunlop, and after passing successfully through a course of architecture at Cornell University entered the office of Mr. Perry, the supervising architect of the New York State Capital, at Albany, N. Y., where he remained for two years, leaving there to further his studies in New York City, where he held positions for two years in the offices of Robt. H. Robertson and Bremner & Tryon. Mr. Robertson, associated with Mr. Potter, was one of the firms selected for the final competition for the Cathedral of St. John the Divine. Mr. Pope will also lend his valuable services to the firm as assistant superintending architect, being thoroughly qualified for this branch of the work.

A pleasing event took place on the 10th inst. at the monthly business meeting of the Stonecutters' Section of the Toronto Builders' Exchange when their late treasurer, Mr. George Walker, was presented with a handsome gold-headed snake wood cane with his name engraved upon it, as a token of the high esteem in which he was held by his fellow members and as an expression of their good wishes on his entering into private life. Mr. John Vick, president of the Section, made the presentation in an eloquent and suitable manner, to which the recipient replied in appropriate terms. Mr. Walker has been connected with the Stonecutters' Association since its establishment about 15 years ago, holding the office of treasurer, which he resigns on retiring from an active and successful business career. Mr. John Barnard, his late partner, succeeds him in the office of treasurer to the association.

QUESTIONS AND ANSWERS.

[Readers are invited to ask through this department for any information which they may require on lines consistent with the objects of the paper. Every effort will be made to furnish satisfactory answers to all such inquiries. Readers are requested to supply information which would assist us in our replies. The names and addresses of correspondents must accompany their communications, but not necessarily for publication.]

"BUILDER" writes: How can you find the pitch of a roof by multiplication?

Ans.—If ½ pitch is required multiply span by 71; if ¼ pitch by 556; if ⅓ pitch, by 6; if ⅜ pitch, by 625, and if ⅝ pitch, by 8.

T. N.: How many nails are required for 1000 laths, and how many yards of plastering will cover this number?

Ans.—Eleven pounds of lath nails and 70 yards of plastering may be estimated.

ART MAXIMS.

THE following verses, kindly sent to us by a correspondent, are from the poems of William Watson, who wrote the best ode on the death of Tennyson, and it was thought might succeed him:

Often ornateness
Goes with greatness;
Oftener felicity
Comes of simplicity.

Talent that's cheapest
Affects singularity;
Thoughts that dive deepest
Rise radiant in clarity.

Life is rough;
Sing smoothly, O Bard!
Enough, enough,
To have *found* life hard.

No record Art keeps
Of her travail and throes.
There is toil on the steeps,—
On the summits, repose.

LEGAL DECISIONS.

At the Hamilton assizes a labourer brought an action for $1,500 damages against Mr. Joseph Kent, contractor, of that city, under the Workmen's Compensation Act. It appears that the plaintiff was employed in building a sewer in November last, and while removing some boards the side of the trench caved in and the plaintiff was seriously hurt. It was claimed by him that the trench was improperly shored up. The defendant, however, gained a verdict in his favor.

In Cook v. Belshaw the question is raised whether a mortgage, registered before a lien but not made until after the attaching of the lien, can be considered a prior mortgage of such a nature that the lien-holder could avail himself of the benefit of the provisions of the Lien Acts, giving him priority for the amount to which the selling value of the land was increased by the lien-holder's work or materials. The Master-in-Ordinary held it was a prior mortgage in this sense, but his decision has been appealed against.

Caldwell v. Mills was an action under the Workmen's Compensation Act brought by J. Caldwell against Geo. E. Mills, contractor, of Hamilton, for $2,000 damages for injuries. The plaintiff, it appears, was carrying scaffolding across a plank when the plank broke and he fell into a cellar, breaking three of his ribs. It was alleged the plank was rotten, but the defence was that the plank broke by another workman throwing a heavy piece of scantling on it when the plaintiff was crossing. Verdict for the plaintiff, $75; the question of costs being reserved.

JONES v. TORONTO SCHOOL BOARD.—The plaintiff carried out certain works for the defendants under a contract which contained the usual clause to the effect that no extras would be allowed unless the work was executed under the written authority of the architect. Certain extra work was carried out without such authority, but the architect allowed a certain sum for same, and when the job was completed the plaintiff accepted in full of all claims a cheque setting out the amount of contract, the claim for extras and the amount allowed for such by the architect. After the lapse of two years the plaintiff brought the present suit claiming the balance of the extras as charged by him. The case was heard by Chief Justice Armour, who dismissed the action without calling upon defendants, because plaintiff could not produce any written authority for the extra work as called for by the terms of his contract.

EVANS v. COWAN (two cases.)—In this case the plaintiff invited tenders separately for the stone foundation, brickwork and carpentry to a large building to be erected in Montreal for a skating rink. The defendant's price for the brickwork was accepted, and a contract was entered into upon the usual terms. When the foundation work was finished, the brickwork to the walls was started by Cowan, but after constructing a part serious defects showed themselves in the work which the defendant alleged was due to the bad construction of the foundation. Evans ordered the work to be pulled down which Cowan did, but refused to rebuild. After protests and counter protests between the parties Cowan took action in the Supreme Court, asking to have his contract declared at an end, that the plaintiff be condemned to pay him $1,000 damages, and allow him to remove all his building materials. About the same time Evans entered a suit against Cowan for $3,850 damages for non-completion of his contract. The two actions were heard together before Mr. Justice Matthew, who gave judgment in favor of Cowan in both cases, on the grounds that the evidence showed the foundation to be defective, and, as Evans provided that work, Cowan was not obliged to accept and build upon it. Appeals were taken against both judgments and the higher Court decided in favor of Evans in both suits, holding that there was no clear evidence that defects existed in the foundations for which Evans was responsible.

A committee has been formed in Toronto, with Mr. A. M. Cosby, 66 King E. as secretary, to raise $2,000 by subscriptions for enlarging the dials of the clock in the tower of St. James Cathedral to a diameter of 15 feet, and lighting same by electricity.

THE PROPOSED AMENDMENT TO THE LIEN LAW.

SIR Oliver Mowat has introduced in the Ontario Legislature, a bill entitled "An Act to further Facilitate the Enforcement of the Just Rights of Wage-earners and Sub-contractors." Its principal clauses read as follows:

1. Every device by any owner or contractor which shall be adopted in order to defeat the priority of wage-earners for their wages under the several Acts relating to mechanics' liens shall, as respects such wage-earners, be null and void.

2. In case an owner chooses to make payments to the mechanics, labourers, or other persons referred to in the 4th section of the revised *Mechanics' Lien Act*, for or on account of just debts due to them for work done or materials or machinery placed or furnished as therein mentioned, without the proceedings mentioned in sections 11 to 14 of the said Act, and shall within three days afterwards give by letter or otherwise, written notice of such payment to the contractor or his agent, such payment shall, as between the owner and the contractor, be deemed to be a payment to the contractor on the contract generally, but not so as to affect the percentage to be retained by the owner as provided by the sections 7, 8 and 9 of the said *Mechanics' Lien Act* as amended by the Act passed in the 53rd year of Her Majesty's reign, intituled *An Act to amend The Mechanics' Lien Act.*

3—(1) Before a contractor shall be entitled to receive a payment on his contract, it shall be his duty to produce to and leave with the owner, his pay list or a duplicate of his pay list, containing the receipts of the persons mentioned for the wages due to them up to and including the day before the intended payment, and an affidavit or statutory declaration by the contractor, (or in his absence by his agent competent from personal knowledge to speak to the facts), verifying such pay list and receipts, and stating that the said pay list names all persons employed on the work, and that all persons who up to that time have been employed on the work and entitled to wages, have been paid in full; and an affidavit or a statutory declaration to the same effect by the architect or superintendent of the work (if any), unless he has made the like affidavit or statutory declaration under the provision aforesaid as to an agent. The said affidavits or statutory declarations may be to the effect set forth in the schedule to this Act, and marked A.

(2) The said pay list so receipted and the said affidavits shall be conclusive evidence in favour of the owner making the payment unless at or before making the payment he had actual and express notice of any fraud on the part of the contractor in obtaining the signatures and receipts of the persons named in the pay list or others.

(3) Any payment made on the contract without having received such receipted pay list and affidavits, or with actual and express notice of unpaid wages, shall not be a valid payment as against persons whose wages are unpaid at the time of the payment on the contract.

4. The lien of wage-earners for thirty days' wages, or for a balance equal to thirty days' wages, provided for by section 9 of the *Mechanics' Lien Act*, as amended by section 2 of the said Act intituled *An act to amend the Mechanics' Lien Act*, shall not be defeated or impaired by any attachment issued subsequently to the contract, or by any garnishment subsequently had, or by any execution subsequently issued, or by reason of the work contracted for being unfinished, or of the price for that or any other reason not being payable to the contractor.

5. In case of the contract not having been completely fulfilled when the lien is claimed by wage-earners, the percentage aforesaid shall be calculated on the work done or materials furnished by the contractor.

6. Where a mortgage is given to secure an intended loan of money which is to be made thereafter according or with reference to the progress of work done, or materials or machinery placed or furnished as aforesaid, on the land mortgaged, no advance thereafter made by the mortgagee shall have priority over the claims of mechanics, labourers, or other persons referred to in section 4 of *The Mechanics' Lien Act* as aforesaid if the mortgagee at or before the time of such advance has actual and express notice that there are any such claims as aforesaid unpaid; nor unless at the time of the advance he shall require and receive from the mortgagor an affidavit or statutory declaration stating that all such persons as aforesaid have been paid in full up to the time of the advance; and an affidavit or statutory declaration by the architect or superintendent of the work (if any), speaking to the best of his knowledge and belief to the same effect. The said affidavits or statutory declarations may be to the effect set forth in the schedule to this Act, marked "B."

7. In case of the sale or mortgage of an unfinished house or building, with or without the land on which the same stands, if its being an unfinished house or building is such as to be apparent to an ordinary observer, the purchaser, before paying his purchase money, or giving a mortgage or other value or security for any balance of such purchase money, or the mortgagee before advancing any money on the security of a mortgage or otherwise, shall require from the vendor (in the case of a sale) or from the mortgagor (in the case of a mortgage) similar affidavits or statutory declarations of the payment of all claims as are provided for in section 6 of this Act; and the purchaser or mortgagee shall not be entitled to priority in respect of such claims, if at or before the time aforesaid he had actual and express notice that there were such claims as aforesaid unpaid, nor unless he shall have received such affidavits and statutory declarations aforesaid.

8. Where in the case of a prior mortgage or other charge, the selling value of the land is increased by the construction alteration, or repairs of the building, or by the erection or placing of the materials or machinery on the said land, the said prior mortgage or other charge shall retain its priority to the extent of the value or amount for which such prior mortgage or other charge is a security before such construction, alterations or repairs of such building, or before the placing of such materials or machinery on the said land; and the lien given by the said Acts shall be entitled to rank upon the increased value given to such land by the said improvements in priority to such mortgage or other charge (see R. S. O. c. 126, s. 5, sub-sec. 3, and *Kennedy* v. *Haddon*, 19 Ont., R. 240; *Richards* v. *Chamberlain*, 35 Grant 402, and *West* v. *Sinclair*, 28 Canada Law Jour. 119.)

9. Where any proceeding is taken to enforce a lien under the *Mechanics' Lien Acts*, in case a mortgagee of the land is served with a written notice of such proceeding being had, he shall thereafter be entitled to attend the proceedings: and in such case he shall not, without the leave hereafter mentioned, take any proceeding for sale or foreclosure, nor proceed to exercise any power of sale until the proceedings to enforce the lien have terminated; but he may without leave serve any notices required to be served in order to the due exercise of the power. The leave aforesaid may be granted by the county judge, master or official referee, before whom the lien proceedings are pending, and shall only be granted by consent, or (if without consent) on a reasonable consideration of all the circumstances in view of what would be just to both parties.

Clause to to the end of the act deals with provisions for legal proceedings. They give the Division Court and City Magistrate jurisdiction in matters relating to the payment of wages, and any order made by the latter can be made a judgment in the Division Court and enforced as such.

On the 8th inst. a deputation from the Toronto Builders' Exchange, consisting of Messrs. John Aldridge, David Williams, M. Murphy, William Park, Wm. Pears, George Moir, M. Vokes and James Tennant, with Messrs. G. Ritchie and Frank Denton as legal advisers, waited upon the Ontario Government with regard to the above act. The deputation was introduced by D. Gilmour, M.P.P., and received by Sir Oliver Mowat, Hon. A. S. Hardy, C. F. Fraser, John Dryden and G. W. Ross. Mr. Pears, President of the Exchange, in speaking on behalf of the delegation, said that the bill as it stood would adversely affect legitimate business to a greater degree than it would remedy an injustice supposed to exist affecting wage-earners. He referred to certain amendments which the association he represented desired to see made to the bill before it became law, and said as regards section 1 he thought it should read so as to apply to the same parties mentioned in section 4 of the "Mechanics' Lien Act" viz: every mechanic, machinist, builder, miner, labourer, contractor, or other persons doing work upon or furnishing materials to be used in the construction of a building. He considered the supply merchant had as much right to be protected from devices to defeat payment for materials as workmen for their wages. Section 2 he found no fault with, but section 3 he considered embodied the chief weak point of the bill. It was almost impracticable, and should be struck out as absolutely unnecessary, while section 6 remained. It did not even reach the parties it was intended to, and would greatly hamper the business of a legitimate builder. He believed that any workman who had lost wages could show that it was not because the contractor had received his money and had not paid off his workmen, but because the latter had not been able to get his money from the building owner, and the section would not reach this man. These were the cases where workmen lost their wages, or when the builder and owner were the same person. He could honestly say he had never heard of a man not being paid by a contractor when the contractor had received what was due to him. Section 4 was considered just, but section 5 should include the same parties suggested for section 1. He would also propose that the percentage retained on a contract should be applied to the liquidation of liens before being used for completing the building. The objects which it was hoped section 3 would attain he thought, as already suggested, would be amply provided for by section 6, and therefore this and the following section should stand while section 3 should be expunged. With regard to section 8, he considered an amendment should be added to the effect that the value of improvements referred to should be estimated at 50 per cent. of their actual cost; thus while 50 per cent. would go to the mortgagee, there would be also 50 per cent. of their value available to satisfy any existing liens upon the building. With regard to the jurisdiction of matters under the act, he thought that the Division Court should be the legal tribunal for liens, even those now provided for in the High Courts by the "Mechanics' Lien Act," and he asked that the Bill be allowed to cover this ground. In conclusion he wished it to be understood that the object of the delegation was not to prevent justice being done to the wage-earner, but that both classes should be placed on a fair and equal footing in their business connection.

Mr. John Aldridge also pointed out that section 3 which was aimed at speculative builders, would not touch that class to any extent, as such men were generally building owner and builder combined. If the clause was allowed to stand as at present it would only be the means of hampering the work of legitimate contractors. He doubted very much whether it would be possible to produce receipts for all wages paid, as they were not always obtainable.

Sir Oliver Mowat asked if this clause would meet the views of the deputation if it was altered so as simply to provide for the production of an affidavit when an advance was required declaring that all wages due say a fortnight previous to that date had been paid.

Mr. Aldridge in reply thought that the trade would be satisfied with any arrangement as long as they were not hampered in their business, but as the clause would not reach the parties intended he did not see the necessity of it being in the Act.

Mr. Ritchie strongly urged that in clause 5 it should be made quite clear that lien holders had to be satisfied before any of the percentage held by the building owner could be devoted to completing the building.

Sir Oliver Mowat thought the clause was clear on that point.

Mr. Ritchie also drew attention to the fact that no provision was made in cases where a builder purchased land simply on the terms of a building agreement. He therefore suggested a clause should be inserted to the following effect: "In case a purchaser of any land shall make default in carrying out the terms of an agreement for the purchase thereof, a lien shall not be defeated by such default, but shall be attached to the estate or interest of the person to whom the land shall revert by reason of such default." He also thought that claims under the lien laws for wages and materials should be transferred to the Division Court from the higher Courts, as he had often found in his experience that costs prevented the bringing of actions for small amounts.

Mr. Denton agreed that clause 6 in the Act accomplished all that clause 3 attempted to, and therefore there was no necessity to binder legitimate business.

Mr. Aldridge received no answer to his question whether there was a law calling upon a workman to give a receipt for wages, and he again urged it would be impossible to obtain receipts in some cases.

In reply to Mr. Hardy, who stated that the journeymen complained of the loss of large amounts of wages, Mr. Vokes pointed out that these cases probably arose from men working under an agreement very common among small builders, which provided that the wages for the work be paid when the building was completed and sold. If it was not disposed of the workman did not get his wages, and he probably considered it was a hardship overlooking the fact that he undertook the work with a clear understanding of the risk. After some further remarks from Mr. Hardy the deputation withdrew, having received a promise that the questions raised should receive every consideration.

CONSTRUCTION OF HARDWOOD DOORS.

IN constructing the modern hardwood door, a series of operations are gone through by the cabinetmaker which are extremely interesting and of value to those who desire to know something of the methods of construction employed in completing this now universal detail, writes Owen B. Maginnis to the *Building Monthly*. These operations embody a number of systems of proceeding, each aiding to a final end, and are as follows:

The first process is to glue the cores or grounds together. These generally consist of kiln dried white or yellow pine, say 1⅛ inches thick for an 1¾-inch veneered door, the veneers being ⅛ inch thick. The cores are generally got out full enough to allow for facing and thicknessing on the jointer and in the planer. The number of pieces in the cores depends on the desired width of the stile or rail, as, for instance, a 6-inch would require a ¾-inch band of the necessary hardwood, ash, oak or walnut, as specified, and four 1¾-inch pieces of pine.

In glueing these cores together they are carefully jointed with the plane and scratched, then heated in the hot box and at once glued, being pressed tightly together with large hand screws, in order to squeeze out the superfluous glue and close the joints.

In making joints in veneered work the surface of the joint must in all cases be (a little shaving) hollow, for the purpose of allowing the outer arises to come close together. Of course, all the cores should be long enough to make the necessary height, as 7 feet 8 inches long for a 7 feet 4 inches door, and so on as needed, always allowing enough to round over the bottom ends, so that the veneer will not be torn off when moving the door. When the glue is set the surfaces are scraped off clean, and they are faced up perfectly out of wind of the jointer and afterwards tried up true with the try plane. This being done the stiles and rails, which are built up in the same manner, are brought to the planer or planing machine and there thicknessed. The stuff cores are then brought back to the bench, where they are surfaced as before with the try plane (to remove all lumps) and scratched with the scratch plane to form a keying for the veneer. All knot holes or flaws which might be liable to cause a defect in the veneer are carefully filled up to insure good veneering. This being done, it is usual to prepare the veneer after it has been ripped to its necessary width and crosscut to its length—that is, the different pieces for the stiles, rails, muntins, etc.

It is usually prepared by smoothing the poor side (being very careful that it is entirely free from spots or shakes, little knots or other flaws) and scratching it thoroughly to insure a firm keying for the glue. All the pieces (which generally run from ⅛ thick up to ½) are placed between strips edgeways in the hot box, and allowed to become thoroughly impregnated with the heat so as to keep the glue from cooling too quickly, besides opening the pores of the wood to admit it. While the veneers are in the box the cores are placed (the stiles first, in pairs) on the glueing horses and the big handscrews set ready for applying, keeping the jams wide enough apart to take in two pairs of 2-inch stiles, or eight inches, or six inches, for one pair of 3-inch, and so on as required. When the veneers are sufficiently heated the flat faces of the cores are glued both sides and turned up on their edges (hardwood strip side up) slightly apart, and the veneers are dropped between.

Be sure, however, to have the points of the grain up, to have the grain running up, and to have the grain so that they will pair alike. This should always be done before placing the veneers in the box. Having placed the cores of the stiles on the edges to which the hard wood strips is affixed the woodworker takes his veneer and after carefully matching the grains places them grain points up with the scratched side towards the glued faces of the cores resting on the horses so that the edges of the veneers and cores will come fair. He will then place a veneer on each of the right and left outer faces of the cores. Having done this he places a cawl or piece of 1¼-inch stuff on each outside to press the outer veneers against their ground, and takes the big hand screws which have been set to span the combined width of cores and veneers. He places one at either end about two inches from the end spaces, the rest eight or ten inches apart, applying each screw from opposite sides. He screws the inner throat screw till it grips on the edge, and then turns the outer lever screw solidly down on the cawls, thus pressing the surfaces tightly together and forcing the glue into the scratches, at the same time driving out that which is superfluous. Before the screws are permanently screwed tight, the whole mass is turned up to see that the veneers completely cover the whole width of the surfaces and if they do not they must be driven to their places with a block, taking care not to bruise or break the edges. Be certain, too, that the screws are all tight and the veneers pressed to a perfectly close joint.

It is best for two to veneer, for one can regulate the veneers while the other is applying the screws, and both can act together on the screws afterward, giving more power. The glued stiles or mullions are then left in the screws about five hours to allow the glue to set.

Let me here impress the fact that the stuff must in all cases be thoroughly heated, and the glue perfect glue (about one-third water and two thirds glue) laid on quickly with a large soft brush from a large pot, also that the operation be rapidly done before the stuff has time to cool.

The cawl must be only the exact width of the stuff and no wider. It is advisable that the jaws of the hand screws be also wide enough to reach across the width.

SCARFED BEAMS.

Where neatness is more essential than strength, scarfed joints are prefrred to any arrangement of "fishing," because a beam united by scarfs and bolts is of the same breadth and depth at the joints as at other parts. In order that the bolts may not be screwed through the timber and to increase the clamping surface, it is advisable to add a plate of iron on the faces of the beam where the heads and nuts of the bolts pass through. The ends of these plates may be turned into the wood to give greater grip. But it is desirable to avoid depending solely upon bolts for the strength of a scarf, owing to the effect of the shrinking of the timber and the liability of the bolts to be, in consequence of their small dimensions, pressed into the wood. Keys or wedges can be often used to keep the upper and lower parts in their places. Varieties may be almost infinitely multiplied by increasing the number of the faces, whether oblique or square, and uniting the parts either by tabling, keying or a combination of the two; but in most cases, the greater simplicity should be aimed at, in order that the parts may the more readily be made to fit each other with accuracy. Very complicated scarfs have been used by some old carpenters, respecting which Robinson observes that "many seem to aim at making the beam stronger than if it were one piece," an absurdity too manifest to need refutation. When a scarfed beam is exposed to transverse strains, the joint should be varied from the ordinary form. When a piece of timber, subject to compression in the direction

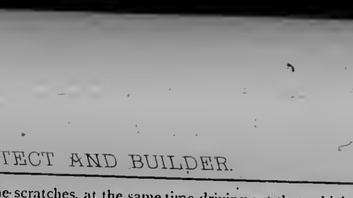

FIG. 2. Showing Joints, Track &c.

of its length, has been scarfed, oblique faces should be avoided because of their tendency to slide upon each other.

Though bolts are commonly used to secure scarfed joints, iron hoops or straps, driven on tightly, have been recommended in their stead and posess the advantage of not weakening the timber. In joints that depend wholly on bolts, Tredgold recommends that the sum of their areas should never be less than two-tenths of the area of the section of the beam. He has also given the following rules for the length of scarfs: In oak, ash or elm, the whole length of the scarf should be six times the depth or thickness of the beam, where there are no bolts. In fir without bolts, twelve times the depth. The whole length of a scarf dependent wholly upon the bolts, should be for oak, ash or elm about three, and in fir, six times the depth of the beam. When bolts and indents are used together, the length of the scarf may be in hard wood twice, and soft wood four times the depth.—*The Architect.*

New buildings to the value of nearly $2,000,000 are said to be in course of construction at Winnipeg.

TESTS OF WHITE PINE.—Some tests of the tranverse strength of small pieces of pine made by Mr. James W. Woodman, of the Minneapolis Building Inspector's force, and published below, indicate the wide variation existing in the strength of different samples of that wood. All but two pieces were from different boards, and as they were taken from the refuse of a large factory there is small chance that any two except those mentioned above were from the same tree. All were as carefully gauged and squared as possible with joiner's tools, and the loads were applied slowly. Thirteen pieces one inch by one-inch, twelve inches between bearings and loaded at center, broke as follows?

1,420 pounds	4,464 pounds	7,795 pounds	10,540 pounds
2,580 pounds	5,610 pounds	8,280 pounds	11,370 pounds
3,450 pounds	6,530 pounds	9,295 pounds	12,420 pounds

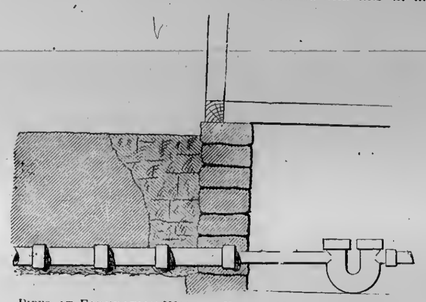
13,210 pounds

The average breaking strength being 420 pounds.

SANITATION AND HEATING

EARTHEN PIPES AT FOUNDATION WALLS.

THERE is frequently asked a question in regard to stopping earthen pipes outside the foundation walls which is now always answered in a satisfactory manner. A man laying earthen pipe, unless he has strict orders to the contrary, is inclined to carry it to the inside face of the foundation. When left in this condition, the plumber carries his house drain into the earthen sewer, covers the joint with a good supply of cement (which in a great many cases only covers the upper half of the pipe), and the work is considered complete. Then follows the mason who points up the opening made in the stone work, very much as we have shown in Fig 1. There is no fault to be found with this at the



PIPES AT FOUNDATION WALLS. FIG. 1.—UNSAFE CONNECTION.

time of construction, provided the plumber has succeeded in making a tight joint between the earthen and iron pipe.

If the house has an area, as shown in Fig 2, the earthen pipe or house sewer is usually brought inside the area wall and left nearly flush with the outside wall of the foundation. The concrete of the area is laid down over the earthen pipe, and the area wall is pointed up. This is, like the former, a good job while it is new, but it is very objectionable when carried out in the way shown for this reason: The excavation is always made somewhat larger than the wall, and the wall itself, sitting on fresh soil, is liable to settle. Even the light area walls have considerable movement. In addition to this, the dirt behind them (as shown in the figures) is loose, and after rains usually goes down sometimes to the extent of several inches. The walls being cemented close around the earthen pipe, go down with the dirt, and the result is either the cement around one of the joints of the house sewer is spit or broken or the pipe itself breaks. This break being on top is not readily discovered, but at the most dangerous place in the whole house it permits the entrance of foul gases into the basement of the building from which they will be carried by the natural currents into all parts of the house. In case there is an area the danger is usually quite as great, because the area wall is built with less care, and

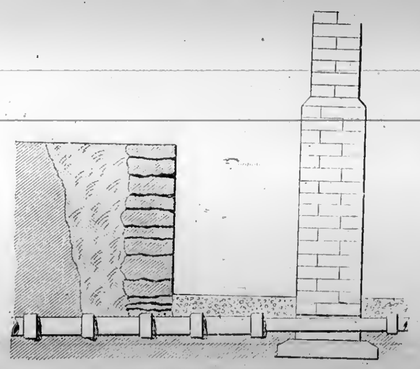


FIG. 2.—ANOTHER UNSAFE CONNECTION.

settlements under the action of frost and rain are much more common than in foundations. These settlements are also greater in extent. It was probably for this reason that the New York city plumbing rule calls for the iron pipe to extend two feet outside of the outside face of foundation or area walls through which the pipe passes.

In cities where earthen house drains, as well as earthen sewers are allowed, the trouble from settlement is just as great as in the two cases mentioned. But it is possible to overcome this difficulty if proper precautions are taken. These precautions are simple and not at all costly. If the pipe passes through an opening so arranged that the settlement of the wall cannot affect the pipe, the object is accomplished. If, as in Fig 3, at the foot of the foundation wall a flag stone, or other foot stone is arranged, so as to support the wall, at the same time leaving an opening for the pipe to pass through, the settlement will be provided for without throwing any pressure upon the pipe at one

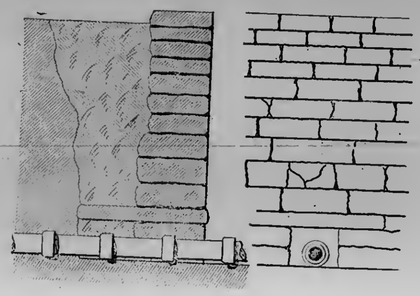

FIG. 3.—A SAFER METHOD.

point, and the pipe, not being disturbed, will be safe. This precaution can be taken at area walls equally well, and the result is the safety of the pipe at a critical point. When pointing it must be kept in mind when carrying the pipe through a wall in this way, that is, if the hole where the pipe comes through is cemented up solidly, as is sometimes done, the advantage of having an opening or arch which might be used instead of the flat stone, all the advantages will be destroyed. Hence this opening should be filled up loosely and only the very face of the wall closed with cement in sufficient quantity merely to keep out vermin.—*Metal.*

INSANITARY CONDITIONS IN MONTREAL.

MR. R. P. Fleming, speaking as to the sanitary conditions in Montreal, says that the serious defects found in houses examined for the first time reaches 83 per cent. The inspection referred to was among large houses in the best part of the city, so that this gives no idea of what may exist among smaller properties where the inhabitants have to depend upoo the owners and authorities for a proper condition of things. In his report to the Montreal Sanitary Association on this subject, Mr. Fleming particularizes cases of defects of various characters, such as bad plumbing and pipe laying, but in almost all the cases sewer gas has direct access to the interior of the houses. It is surprising that such a state of things could possibly exist in a city like Montreal. In a large house in the best part of the city the soil pipes were found simply laid in without any jointing of any kind, and one two-inch pipe, perfectly open at the end, was discharging volumes of sewer gas into the house. Besides this the cess pool was situated directly under the kitchen where the servants lived, worked and cooked. The report closes by calling upon the association to take further steps to urge the City Council to provide proper inspection and supervision of all sanitary arrangements. It is hoped the petition which the Sanitary Association have prepared, when presented to the Council, will be acted upon.

PUBLICATIONS.

A number of the best designs submitted in the recent Presbyterian church competition, accompanied by descriptions, essays on church architecture, etc., will be published shortly in pamphlet form.

We have received from Mr. Samuel Cabot, the well known manufacturer of shingle stains, an artistically colored lithographic view of his factory in Boston, Mass., which is described as being the largest establishment of its kind in the world.

The *Cosmopolitan Magazine* scores a success in producing in its May number, almost simultaneously with the daily papers, an elaborate description of Professor Gray's marvellous invention, the Telautograph, which reproduces the handwriting, or the work of the artist, simultaneously, thousands of miles distant from the place where the writer or artist is sitting.

The Sunshine Publishing Company of 402 Race street, Philadelphia, have published a work entitled the "History of the Master Builders' Exchange of the city of Philadelphia." The work is compiled for the historical committee of the Exchange by Clem. H. Congdon, and gives an interesting and concise account of the institution since its organization in 1886. The leaves of the book are interseeted with over 50 illustrations dealing not only with matters relating to the Exchange, but also by a series of good cuts taken from photos of models exhibited at the Paris Exhibition in 1889, showing the different class of habitations in the principal countries of the world. The book should be in the reading room of every Builders' Exchange.

At the recent examinations of the Toronto Technical School, Messrs. W. D. Wilkinson, G. R. Groth, R. W. Ferguson, L. Johnson, D. Eagle, E. Sauton, E. Cannon, E. H. Richards, and F. R. Love were successful in the subject of Architectural Drawing, and Messrs. W. E. McMullen and G. R. Groth, in Perspective Drawing.

MANUFACTURES AND MATERIALS

LIME AND CEMENT.

THE powder produced from pure and impure limestone by means of heat is called lime or cement, and, as materials used in the masons' and builders' art, they are classified as common or fat lime, hydraulic lime and hydraulic cement. Good lime is in hard lumps, free from cinders, clinkers, much dust, and should form a very smooth paste when slacked. The limestone from which common lime is obtainable is very seldom pure, and contains magnesia, alumina, silica, and similar impurities to the amount of from 3 to 10 per cent. The paste it makes is greasy, from which fact it is known as "fat." It is sometimes called "air-lime," as it will not harden unless it is exposed to the air, and, if mixed with water, it can be kept for an indefinite period without loss of its qualities, provided it is kept from contact with the atmosphere.

Hydraulic lime differs from common lime in that it will harden under water, which is on account of its clayey or flinty nature. When burnt it becomes a caustic lime, and on being brought into contact with water is hardened, its hydraulicity being produced by the crystalizing elements of the clay and flint in the lime. This lime is imported in large quantities from France, but an artificial material of this class can be made by mixing unburnt clay with common lime or a powdered limestone, burning in the shape of bricks by means of a common kiln, slacking the material in the ordinary way, care being taken that there are no lumps of clay still unburnt.

Hydraulic cements are of three kinds, viz.: Portland, Rosendale, and Pozzuolana, but the last named is seldom used, as the strength of the cement is much less than others of this class. It, however, is an ancient cement, being used prior to the Roman age, and it was the first cement known to possess the property of hydraulicity. Its name is taken from the place where it was first found, viz, Pozzuoli, in Italy.

Rosendale cement, sometimes called "natural" or "American," is found and largely used in the United States. The natural bed of limestones from which this cement is made covers about one-third of the State of New York and other parts of the country, and is of a clayey, magnesium nature, light and quick setting.

Portland cement obtains its name from its resemblance when made in a hardened mortar to stone found on the isle of Portland, off the south of England. It was first made in that country in 1843, and in America in 1874, and is heavy, slow setting and of great ultimate strength. The natural stone from which the original Portland cement is made contains 20 to 22 per cent. of clay and 78 to 80 per cent. of carbonate of lime, and its superiority is increased by the intensity and duration of the heat employed in burning, which is almost to the limit of vitrification. Artificial Portland cement is very largely used, and about nine out of every ten of this class of cement now in the market are not the genuine article. Some of these cements, however, are equal to the best imported Portland, and with proper care a still better cement might be obtained. It is generally made by mixing in proper proportions clay and chalk, marl or compact limestone, and burning them at a high heat.

The testing of cements is an important matter, as their values vary to a large extent, and the natural properties of one portion of a cement are liable to differ from another portion, although of the same brand. Particular attention should be paid to the soundness, fineness and strength of a cement. It should be sound, so as not to expand or contract in setting, which is caused by active lime or magnesia being in the material. The presence of such impurities can be proved by immersing in water some cement mortar with very thin edges, and on examination after say two days, the material will be found contorted and cracked at the edges. The magnesia is more harmful than the cement, for the latter can be slacked by exposure to the air. Many defects in masonry buildings of recent years have been caused by the hydration of magnesia in the cement. It is well to remember in testing the soundness of cements that the trial should extend over considerable time, for some defective material will stand for a period, and then lose its unity and fall to pieces.

Fineness in cement is essential from a point of economy, for the finer the cement the greater will be the surface it will cover. It should also be borne in mind that cement will not crystallize by the addition of water unless it is ground, because the coarse particles have no binding power. In order to determine the fineness of the material; sieves are employed with a certain number of meshes to the square inch—one with 50 is considered a good test, and the cement that passes through is of a recommendable fineness.

The strength of cement is usually determined by submitting a specimen in solid form to a tensile strain, for should it pass this test the compression will also, as this material is not so strong in tension as in compression. The committee of the American Engineering Society recommend that the tensile stress applied should increase at the rate of 400 lbs. per minute.

There are other properties, such as color and weight, which are often tested when determining the value of cements, but they are not of so much importance as the matters already referred to. Color indicates the difference in the character of the rock and amount of burning. Gray or greenish is considered a good color, while bluish gray indicates a probable excess of lime, and brown the presence of much clay. American cements are peculiar in respect of color, they generally being of a light or dark brown shade.

Weight of cement varies according to the heat given in burning, fineness in grinding and density of packing. The harder a material of this class is burnt the more it weighs. The time a cement takes to set may be also considered a test as to its quality, and one that sets in 30 minutes or fails to commence to do so within three hours, reckoned from the time the water is poured upon the cement, should not be used.

DUTY ON CEMENT.

Deputations representing the manufacturers of Canadian cement and the Canadian importers of foreign cement have recently waited upon the Government with reference to the import duty of 40 cents per barrel. It is the desire of the former that the duty be allowed to remain as at present, while the latter urge that cement be placed on the free list. The imports of cement into Canada last year amounted to 185,000 barrels, while the amount produced in Canada reached 45,000 barrels. The Canadian manufacturers say that if the duty is retained they will soon be able to supply entirely the Canadian market.

Messrs Carroll, Vick & Co., of Toronto, having discovered in abundance on their property at the Forks of the Credit the materials necessary to the production of fire and paving bricks, will shortly enter into these lines of manufacture.

A manufacturer of British Columbia shingles who has recently made a tour of Manitoba, Eastern Canada, and the new England States is quoted as having said that in Ontario people have not yet discovered that it is cheaper to pay a little more for British Columbia shingles and have a good roof for years, than to buy cheap pine shingles, and have to repair continually. A considerable disparity in price as compared with the product of eastern mills is unavoidable so long as the cost of freight remains as high as at present. On the other hand British Columbia shingles are being sold at slaughter prices in Winnipeg and throughout Manitoba, while the American duty is such as to render it impossible to compete with United States mills in the American market.

Builders and contractors of Niagara Falls, N. Y., are endeavouring to prevent Canadian contractors from securing contracts on their side of the river.

Messrs. Taylor Bros. of the Don Valley Pressed Brick Works, Toronto, have sent two car loads of their brick to Chicago, to be used in constructing a building in the Canadian Department of the World's Fair.

The Toronto Roofing company has assigned to Mr. W. A. Campbell, liabilities $1,700, assets $900.

An exhibition composing virtually a history of ecclesiastical art, is to be held in London, England, this year.

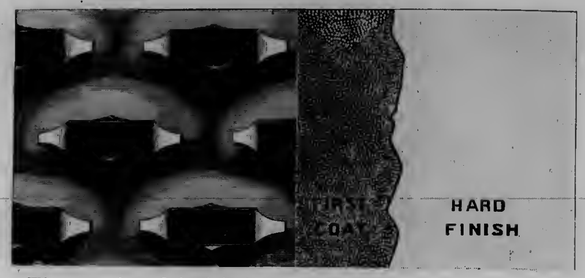
Knox church at Montreal is to be superseded by a new structure. This church was organized 107 years ago, and its first place of worship was erected in 1792 at a cost of $5,250. In 1865 a new edifice was built, and this is now to be pulled down for a new and more imposing structure.

The Master Stonecutters' Section of the Toronto Builders' Exchange have renewed their agreement with the journeymen masons. It is to continue in operation for three years, and the wages to be paid are fixed at 43 cents per hour. Representatives from both parties are to hold a meeting four months before the agreement expires to discuss how the trade stands, and three months notice must be given by either parties before the expiration of the three years if it is their intention not to renew the agreement.

The Confederation Life Association's new building in Toronto was formally opened on the 10th inst. by a luncheon which was attended by many of the prominent business and professional men of the city. The new building, which was the subject of much favorable comment, has cost up to the present about $420,000, and it is estimated that not more than $50,000 additional will be required to be expended for its completion, thus bringing the total cost within half a million dollars. The slow burning principle of construction has been employed.

The Canadian Society of Civil Engineers have appointed the following officers: President, E. P. Hannaford, Montreal; vice presidents, Thomas Munro, Coteau Landing; P. A. Peterson, Montreal; and W. T. Jennings, Toronto; Treasurer, H. Wallis, Montreal; Librarian, William McNab, Montreal. The council also includes H. T. Barrey, St. George Montreal Boswell, Quebec; H. D. Lumsden, Toronto; P. W. St. George, Montreal; J. D. Barnett, Stratford; Alan Macdougall, Toronto; G. C. Cunningham, Montreal; G. A. Mountain, Ottawa; C. K. Donville, Hamilton; C. H. Keefer, Toronto; H. S. Poole, Stellarton; T. Ridout, Ottawa; F. R. F. Brown, Moncton, N. B; E. Mohun, Victoria, B. C.; F. R. Redpath, Montreal.

Hayes' Patent Steel Lath



The tenacity of the bond and other features are unequalled.

Now being used in the "Grand Seminaire," Montreal.

...WE ALSO MANUFACTURE...

Copper, Galvanized Iron and Painted Steel Shingles and Tiles,

Sheet Steel Pressed Brick and other Siding Plates,

Galvanized and Painted Pressed Corrugated Iron.

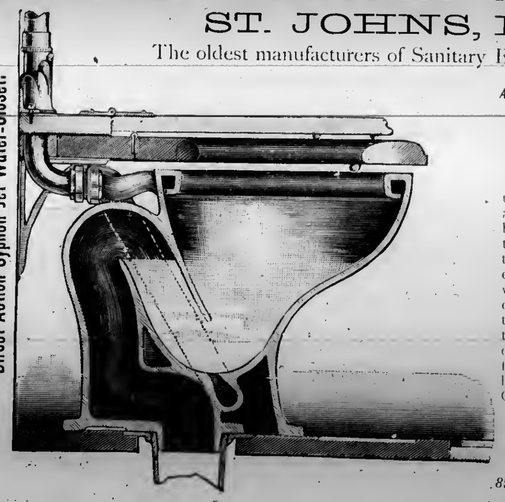
THE "PRIMO"

Direct Action Syphon-Jet Water-Closet.



A full line of all the BEST and MOST POPULAR

CLOSETS, BASINS, etc.

WE have selected this pattern as being one of the best of the Syphon Closets now in use. It is simple, quiet and effective in action, and has four to five inches seal of water in the bowl. The jet, besides the Syphon, acts upon the water in the bowl, facilitating the outgo, so that a limited quantity of water is required for each operation. We make it in white and ivory ware, plain or embossed, and decorated in colors, if desired. We make these Closets entirely in one piece and in one mould, so that there are no seams, as by the ordinary method of manufacture, thus preventing any risk of flaws or leaks from imperfect joints. The very best imported materials are used, and the Closets will not craze or discolor.

CANADIAN ARCHITECT AND BUILDER.

VOL. VI.—No. VI. JUNE, 1893 { PRICE 20 CENTS $2.00 PER YEAR.

—THE—
CANADIAN ARCHITECT AND BUILDER,
A Monthly Journal of Modern Constructive Methods,
(With a Weekly Intermediate Edition—The CANADIAN CONTRACT RECORD),
PUBLISHED ON THE THIRD THURSDAY IN EACH MONTH IN THE INTEREST OF
ARCHITECTS, CIVIL AND SANITARY ENGINEERS, PLUMBERS, DECORATORS, BUILDERS, CONTRACTORS, AND MANUFACTURERS OF AND DEALERS IN BUILDING MATERIALS AND APPLIANCES.
C. H. MORTIMER, Publisher,
Confederation Life Building, - TORONTO, CANADA.
Telephone 2362.
64 TEMPLE BUILDING, - MONTREAL.
Bell Telephone 2299.

SUBSCRIPTIONS.
The CANADIAN ARCHITECT AND BUILDER will be mailed to any address in Canada or the United States for $2.00 per year. The price to subscribers in foreign countries, is $2.50. Subscriptions are payable in advance. The paper will be discontinued at expiration of term paid for, if so stipulated by the subscriber; but where no such understanding exists, will be continued until instructions to discontinue are received and all arrearages paid.

ADVERTISEMENTS.
Prices for advertising sent promptly on application. Orders for advertising should reach the office of publication not later than the 12th day of the month, and changes of advertisements not later than the 5th day of the month.

EDITOR'S ANNOUNCEMENTS.
Contributions of technical value to the persons in whose interests this journal is published, are cordially invited. Subscribers are also requested to forward newspaper clippings or written items of interest from their respective localities.

The "Canadian Architect and Builder" is the official paper of the Architectural Associations of Ontario and Quebec.

The publisher desires to ensure the regular and prompt delivery of this Journal to every subscriber, and requests that any cause of complaint in this particular be reported at once to the office of publication. Subscribers who may change their address should also give prompt notice of same, and in doing so, should give both the old and new address.

THE twenty-seventh annual convention of the American Institute of Architects will be held at Chicago on July 31st, in conjunction with the World's Congress of Architects, referred to in our issue for May.

THE gentleman who for some years acted as quantity surveyor for many Toronto contractors, having recently removed from the city, there would appear to be at present a good opening for a competent man to set up business in this line.

IT seems to have been finally decided by the architect of the new city and county buildings at Toronto, that the buildings shall be completed by day labor, under the immediate supervision of the architect and his clerk of works. This in the case of such an important work is a new departure, and the outcome of the experiment will be the subject of much interest to architects and contractors as well as to municipal corporations and other public bodies in this and foreign countries.

A NO less personage than the general manager of the New York *Herald*, announces by advertisement that he is prepared to receive proposals for plans of construction with estimated cost of a steel office building of from twelve to twenty stories, and that he will pay the sum of $500 for the plans selected as combining the greatest advantages, and $250 for the second best. This, considering its source, makes easily excusable the like exhibitions of ignorance on the part of persons residing in less highly civilized communities to which we have frequently referred. Surely the height of absurdity with regard to architectural competitions has now been achieved.

THE largest hydraulic testing machine in the world is said to be one designed by Prof. J. B. Johnson, consulting engineer in the Washington University at St. Louis. The purpose for which the machine was designed is for use in the experiments being made by the United States Government to determine the strength of commercial woods grown in the United States. The machine can be made to exert a pressure of 1,000,000 lbs. During some recent experiments at the above named University, a piece of timber capable of sustaining 8,000 persons was crushed like an egg-shell when placed in the machine. Brick piers two feet square, columns of granite a foot square, and sandstone three feet square were ground to powder.

THE volume of building operations for 1893 is less in the city of Toronto, as compared with the first five months of 1892, by half a million dollars. Contractors who have been in business in the city for twenty years state that never within their recollection were the conditions so unsatisfactory as at present. Work is being done cheaper to-day with wages at 36 cents per hour than when years ago the rate required to be paid was but little more than half this figure. Scarcity of contracts has engendered competition to an extent which makes it exceedingly difficult for honest work to be done at a profit. Moreover, the financial stringency is such that builders complain that after having fulfilled their contracts, much effort is often required before payment can be obtained.

THE time set for the reception of designs for the improvement of St. Lawrence Market, Toronto, will expire on July 1st. We are not aware what number of architects will respond to the invitation of the Committee of the Council having this matter in charge, but from the indefiniteness which marked the

advertisements soliciting designs we should not expect to see a satisfactory result attained. The subject of the competition is an interesting one. If the Committee would arrange under proper professional advice a competition under clearly defined and proper conditions, something highly satisfactory to the corporation and creditable to Canadian architecture would perhaps be the outcome. Considering however the strenuous efforts which the aldermen have been putting forth of late for the purpose of reducing sufficiently the estimated expenditure for the current year to bring the rate of taxation down to what will be regarded as a not too extravagant figure, it may be considered extremely doubtful whether the expenditure of any money upon an undertaking of this kind will at the present time be tolerated.

PLUMBERS whether rightly or wrongly have obtained the reputation of charging well for their services. The comic papers are accustomed to tell us that to allow the plumber to gain an entrance to one's house is equivalent to placing a mortgage on the property. In view of the manner in which the plumber's desire for profits has been magnified in the press it is not a matter of wonder that in the eyes of the public he should have come to be regarded as an individual whom it is well to keep clear of. It is the duty of the plumber to seek by every means to prove that he is not the extortionist which he has so often been pictured to be. One method of doing this is to watch closely the workmen, and see that they do not charge for more time than is required to do the work upon which they are engaged. Some workmen will bear watching. On more than one occasion recently the writer has seen journeymen plumbers and apprentices stretched out on benches in the public parks, with their kit of tools for a pillow, idling away hours of precious time, which of course is duly charged up to the customer. Such practices are largely responsible for heavy plumbing bills, and for the complaints of extortion preferred against the plumber. In his own interest as well as that of his client the plumber should first personally inspect the work, see what is required to be done, how much time is required to do it, and then give his workmen to understand what is required of them.

IT was perhaps rather a curious coincidence that at the very time the members of the Ontario Association of Architects were endeavoring to get their Bill amended for the better protection of the public against unqualified practitioners or "jobbers" of the profession, there should have been brought up Bills for the purpose of making close corporations of two or three trades. It certainly was unfortunate, for when the House had listened to the arguments of the undertakers, that on sanitary grounds no one should be allowed to bury but a select few who combined for the purpose of keeping the business in their own hands; and to the suggestions that only qualified milkmen should be allowed to sell milk, it became fearful that every separate trade would be seeking to hedge itself in with special statutes. By the time the Bill of the Ontario Association of Architects was reached, the House was in a regular panic, while misapprehension thickened the air like a fog. Under these circumstances the committee in charge of the Bill saw it would be useless to present it, as members of the House were not in a fit state of mind to weigh it on its merits; they therefore decided at the last moment to withdraw it. The O. A. A. therefore remains in *statu quo*, but the work that is being done by it is of too great value to be stopped; the efficient training of capable students is a matter which should be viewed with great interest by the public, and they should be glad to know that the examinations will still be held annually as heretofore, and none will be admitted to membership unless duly qualified.

THE opening of the tenders for certain street paving contracts in Toronto has lately been a subject for a great deal of talk and not a little "flying into print," while the irregularity of the proceedings has opened the door for a great deal of grumbling on the part of "home" tenderers, not upon the merits of the case only, but upon, so to speak, a side issue, namely, the admission of a tender from an "outsider." The tenders were publicly advertised for and ordered to be sent by registered letter through the post. That being the case, to admit a tender in any other way was utterly indefensible and unfair. As is well known, a tend was submitted —"handed in"— after the appointed time, and it was this one that secured the contract. When it was found that such had been the case, the only fair way of dealing would have been to advertise again, that all might have had an equal chance. It is a very great mistake to say that it is for the good of the city that outside tenders should not be admitted. Nothing could be worse than to exclude them; they have many advantages. Tendering is likely to be more honest if not confined to a few. Combines are by this means prevented. Though we should like to see local men doing the work, yet if their prices are so high that a firm from a distance can give us work as good for a lower figure, our "home" tenderers will learn that it is necessary for them to improve their plant and otherwise to put themselves in a position to give the best work for a more reasonable price. But, while favoring the admission of outside contractors on an equal footing with resident contractors, we emphatically protest against any advantage being according to them.

DEPUTATIONS representing twenty town and city municipalities waited upon the Ontario Government a month ago to ask for legislation which would enable them to grant exclusive telephone privileges for a period of five years in return for a percentage of profits of companies to whom privileges might be given. This step was taken in view of the judicial decision recently given affirming the illegality of such action on the part of municipalities. The petition of the deputation was opposed by the legal representative of an automatic telephone company, which was not a matter of wonder. It was altogether surprising and amusing, however, to see a delegation from the Toronto Trades and Labor Council present in opposition to the granting of the required legislation. The telephone has been properly termed a natural monopoly. One efficient telephone company in a town or city is more satisfactory to the public than two or more companies would be. The existence of more than one company makes necessary the renting by every telephone user of as many instruments as there are companies in order that he may be in a position to communicate with every other telephone user. This means additional expense and trouble. It means, so-far as the companies are concerned, that they will be unable to make a fair profit, and consequently will not be in a position to pay any tribute to the municipality. Thus it is that with exclusive privileges granted to one company, telephone users get a better and more efficient service, the telephone company is able to make a fair profit, and the municipality is enabled to exact in return for the exclusive privilege, a considerable percentage of the net earnings of the company with which to lighten the rate of municipal taxation. Strangely enough, there are found people like the Trades and Labor Council, who, while always complaining of their condition, will refuse to allow anybody to assist them in paying their taxes. The legislature, like a wise parent, saw where these short sighted people's interest lay, and granted the municipalities the power they sought for.

A WALK through the older business portions of Montreal convinces one that there is need of very decided improvement in the business blocks there, to say nothing of the narrowness of the streets which, if it is possible, certainly should be attended to. as to the buildings themselves, we may expect to see in the course of a decade considerable changes. Many of the warehouses and wholesale houses are very old and quite unfitted for the business of the day, and consequently the rentals they bring in are very low, and though the majority present very solid stone fronts the interior upon inspection proves to be very much decayed. The handsome blocks of the Grey Nuns warehouses off St. Sulspice street throw the buildings of St. Paul street into the shade. Unless owners bestir themselves and modernize their buildings it is not at all unlikely that the principal business firms will move west. There is indeed a slow and general movement in this direction, and it would be a good thing for the city if, for instance, a few good streets, wide and roomy, were cut through Griffentown, displacing some of the hundreds of poor dwellings that swarm here and are somewhat deleterious to the city's health. The westerly movement is only a continuation of that which has been in progress for the greater part of the century. The quaint buildings to be seen in Hochelaga were vacated in favor of the newer St. Paul street and its surroundings, and these will probably be left for still further west blocks. A feature among the residential streets has been the "tenement houses," which are now rather losing favor. A few years ago it was difficult to get anything else in a decent locality within a mile or a mile and a half from the centre of the city, a "self contained" house being a rarity. These "tenements" were in many ways most objectionable; two families under one roof, the one occupying the basement and ground floor, and the other, with its distinct entrance and staircase, occupying the upper two floors. In this manner a large population could be accommodated in a limited area, but since this was the only means of housing oneself it had to be put up with. So accustomed do people get to circumstances that owners experienced no difficulty in obtaining high rents for "half houses," while many of the best people were willing to occupy them. Now, however, it is hardly likely more of these will be built.

AN article appeared in *The Week* lately on the subject of "class legislation," which is considered by the writer even in the cases of legal and medical societies to be so absolutely unnecessary that any such thing is equivalent to placing the public in the position of "children and imbeciles." It is stated that "ordinarily it will be sufficient that the individuals practising any profession be held strictly responsible for the results of their own incompetency or malpractice"—or in other words it is sufficient to shut the stable door after the horse has escaped. Such is not the spirit of the age, however. We go now on the principle that "prevention is better than cure," and it is surely rather late in the day to argue it is unnecessary for the law to protect the public against imposture because it *ought* to be able to take care of itself. The article in question was prompted by the withdrawal of the Bill of the Ontario Association of Architects for the amendment of their Bill passed two years ago, but the writer betrays his political bias and sneers at reform because it is fostered by those who hold different views to his own. Most of the newspapers have shewn in this connection that this so-called "class legislation" is an absolute necessity, and in the interest of the public should be extended to architects. It is not a case of closing up the profession for the benefit of a few practising architects, but it is for the purpose of enforcing those who will have the lives of individuals in their hands, to prepare themselves by careful study and prove themselves capable by rigid examination to carry out buildings in a manner that shall conduce to the safety of the occupiers. "Official inspection" and "governmental licensing" has and constantly does show itself to be insufficient, insomuch as we continually hear of the collapsing of buildings, and know to our cost of the awful effects of of unsanitary houses and factories. There is a wide distinction between trade unionism and "class legislation," of which however, the writer of the article in question is wilfully ignorant. We notice the article only because of the mischief such thoughtless words may do among those who are easily led by what they see in print, and as we have done so we would suggest to those who may have been influenced by it to use their own common sense and ask themselves how they would feel if through the incompetency of a so-called "architect" they became injured in limb or ruined in constitution for the rest of their lives—whether they would not prefer to have that guarantee that the building they intend to occupy is well built which "class legislation" in connection with the architectural profession would give.

THE estimated expenditure of the City of Toronto for the year 1892 was $1,200,000; this year it is $1,700,000, an increase of half a million dollars. The Toronto Street Railway Company are taking advantage of this circumstance and of the demand of the citizens for a reduction of expenditure to endeavor to secure a change in their agreement with the city. They offer to put down and keep in repair the pavements on the track allowances on condition that they shall be relieved of the payment of the yearly rental of $800 per mile of track as provided for by the agreement. The citizens and their representatives in Council should have no difficulty in discerning in this proposal an attempt to repeat the act of the cunning Jacob towards his brother Esau, and should promptly refuse to give up great and permanent privileges in return for a temporary financial accommodation. The city has already completed more than two-thirds of the permanent pavements, at a cost of a little more than $400,000. It can surely finance and finish the balance of the undertaking and maintain its control of the streets. A comparatively small yearly amount in addition to the rental of $65,000 or $70,000 received from the Street Railway Company would be sufficient to pay the interest on the cost of the pavements, provide a sinking fund for the redemption of the debentures and defray the cost of repairs. So far as the latter item is concerned, it is not likely to prove a very large one. The contractors who construct the pavements will be required under a guarantee to keep them in repair for five years. A concrete foundation may be taken to last fully thirty years, which is the lifetime of the street railway agreement. In some of the busiest streets of London the surface of asphalt roadways last for fourteen or fifteen years. As there would be little traffic upon the track allowances, the surface would not require renewal for even a longer period than that mentioned; therefore, as we have said, the expenditure under the head of repairs is likely to be light. There are other than financial considerations involved, however. For years the city experienced difficulty and expense consequent upon almost constant litigation in the effort to compel the former lesees of the street railway to perform their share of the work of maintaining the streets. Under the new agreement the city has absolute control of the streets, and under no consideration should this control be surrendered.

THE NEW LEGISLATIVE BUILDINGS FOR BRITISH COLUMBIA.

THE Government of British Columbia are losing no time in proceeding with the erection of the new Provincial Legislative Buildings at Victoria. Advices from British Columbia state that the contract for the foundation has already been let at the price of $56,000. The prompt action of the government in this matter will nullify the efforts of the residents of the mainland to prevent the work from going forward and to secure the removal of the seat of legislation from Victoria. The present Government may be turned out of office by the dissatisfied electors at the approaching election, but it will then in all probability be too late to stop the erection of the new buildings.

DETAILS FOR A SMALL HOUSE.

ONTARIO ASSOCIATION OF ARCHITECTS.

A MEETING of the Council was held on June 1st. The report of the committee appointed to obtain legislation amending the Act of Incorporation was received, and the Council approved of the action of the committee in withdrawing the bill of amendment. A circular letter has been issued by the President to the members of the Association stating the circumstances which made necessary the withdrawal of the bill.

* * *

Application to members for the annual fee was postponed until the success or failure of the attempt to procure amendment of the bill had been settled. The Council has decided to keep the fee as low as possible for the next year or two. A schedule has been sent to all members and the Registrar hopes that as the fee is now so small there will be a prompt response that will offset the delay in making the application and that he may be able to return all fees to the Treasurer on July 1st.

* * *

The curriculum for the examinations of 1894 was approved by the Council and has been issued to all students.

* * *

As many students have changed their addresses without notifying him of the change, the Registrar would be glad to receive from every student a post card stating the student's correct address. If by this means it is discovered that any copies of the curriculum have been misdirected second copies will be sent correctly addressed.

* * *

The Registrar begs to remind members of the Association that he has copies of the form of indenture approved by the convention of 1892 and will issue them to all members who require them.

CORRESPONDENCE.

[Letters are invited for this department on subjects related to the building interests. To secure insertion, all communications must be accompanied by the name and address of the author, not necessarily for publication. The publisher will not assume responsibility for the opinions of correspondents.]

Editor CANADIAN ARCHITECT AND BUILDER.

In a recent issue of your weekly edition, the CANADIAN CONTRACT RECORD, "Data for Steam Fitters," 1st item is not correct. A gallon of water contains 276.48, and the weight to lbs. The gallon given in the paper is the old wine gallon and used in the States only. You had an item copied from some other paper last year in reference to the sun taking the temper out of steel tools exposed in shop windows, and I submitted it to a well known firm, makers of fine steels, and they confirmed my own opinion that it was perfect nonsense.

Yours truly,
JOHN H. BIRKETT,
Kingston, Ont.

BRICK EFFLORESCENCE.

Editor CANADIAN ARCHITECT AND BUILDER.

SIR,—We have read with much interest the article in your April issue on the above subject, which is one of considerable importance to brick manufacturers, architects, builders, and every person in any way interested in building.

We must agree with you that the effect produced by the appearance of this efflorescence on the walls of fine buildings, is very displeasing, and it is most desirable that every means should be tried for its prevention.

A variety of opinions seem to exist as to the cause of the efflorescence. So far as our knowledge goes there is no process at present in use which will entirely prevent it. Under certain circumstances it is said that a certain chemical preparation if mixed with the clay will serve to prevent its appearance, but we question if it will do all that is claimed for it.

After having been engaged for twenty-three years in the manufacture of different kinds of bricks, we find that some of the buildings erected with our material will never show efflorescence, while in the case of others, the opposite is true.

There are no bricks made in America to-day which will not effloresce under certain conditions of the atmosphere (except virtified brick) but while we cannot altogether prevent it we should make use of such means as we have of checking it.

We would be glad to hear more on this important suject from some of your readers.

Yours truly,
THE BEAMSVILLE PRESSED BRICK CO.

PERSONAL.

M. Alfred Wood, until recently a designer for Mr. David Roberts, architect, Toronto, is reported to have fallen heir to a very large estate in England.

Mr. B. O'Bryne, late inspector of works on the new legislative buildings at Toronto, is superintending the erection of the asylum for the insane at Brockville, Ont.

Mr. Milton Cathro, a prominent contractor of Toronto, was married on the 7th inst. to Miss Caroline Oswald. Mr. Cathro and his bride left shortly after the wedding ceremony for an extended visit to Chicago and the Northwest. We extend to them our congratulations and best wishes for a happy future.

A severe calamity has fallen upon Mr. Edward Burke, architect, Toronto, whose only son met with an accident which resulted in his death on the 6th inst. The lad, who was about twelve years of age, while riding a bicycle on one of the principal thoroughfares, came in contact with some material which projected from a waggon, and was thrown to the pavement with such violence as to cause a fracture of the skull, resulting in his death a day or two later. The deepest sympathy of many friends is being extended to Mr. Burke and his family in view of the unexpected and severe loss which they have sustained.

AN interesting experiment with shingles was tried a short time ago, says a writer in an English journal. A green 6-inch shingle, fresh from the saw was measured and weighed, care being taken to get both exact. It was found that it weighed 7 ounces. It was then dried and again weighed and measured. It had shrunk nearly ½ inch, while the weight had decreased from 7 ounces to 3. It was then submerged in water 24 hours, and the size had not changed a particle, while the weight had increased about one ounce, demonstrating the superiority of cedar shingles over others, as when once dry they will neither shrink with excessive heat nor pry one another off the roof in wet weather.

QUESTIONS AND ANSWERS.

[Readers are invited to ask through this department for any information which they may require on lines consistent with the objects of the paper. Every effort will be made to furnish satisfactory answers to all such inquiries. Readers are requested to supply information which would assist us in our replies. The names and addresses of correspondents must accompany their communications, but not necessarily for publication.]

W. A. F., Hamilton, writes:

Do you know of any acid or wash that will clean Ohio stone that has been built up for nearly 40 years and is very much discolored?

ANS.—We have no knowledge of any acid or wash which might be effectually used for this purpose, and enquiries made amongst quarry men and stone dealers of large experience met with the reply that the only satisfactory method of cleaning the discolored surface of stone is by re-dressing.

DESIGN IN METAL-WORK.

UNDER the auspices of the Technical Institution Committee, Mr. W. A. S. Benson recently gave an address on "Design in Metal-work" in the Mayor's parlor, at the Manchester Town Hall. Mr. Benson said the two primary conditions that the designer had to acquaint himself with were that metals were fusible, and that they were malleable. It was the combination of these two qualities that distinguished them from other materials so far as structural considerations went. The designer must not forget the nature of metal. As to its strength and tenacity, which enabled thinner sections to be used, that was a mechanical consideration. Then its lustre, so different from any glaze or resinous polish, altered the effect produced by the actual form, so that very different mouldings were required from such as looked well on terra-cotta or oak timber. The brilliant reflective power of polished metal gathered up the lights into points and rings and lines, so that nothing but habitual observation and experience enabled one to forecast the effect of any given form. Nor should it ever be forgotten that when the nature of the work was such that a polished surface could be maintained in high perfection, no beauty or profusion of ornament could compensate for the loss of the mirrorlike beauty of the material itself. The beautiful art of embossing deserved more than mere mention, and that none the less because the very perfection of our technique has gone far to destroy its artistic value. There was perhaps no decorative process which so directly responded to the taste of the craftsmen, which demanded so accurate a feeling for line, for surface and for relief, soft and flowing and yet precise. It was lamentable to see how a piece of genuine Queen Anne or early Georgian silver stood out from the productions of the modern smith, though they in turn were surpassed by many older works. There was no good reason why we should not produce such work again. It only wanted brains and goodwill in the purchaser and the producer. Of course there were some arts which had had their day. We no longer required Damascened sword-blades or etched-steel cuirasses, but we actually did produce, and some paid for, embossed wares by the hundredweight, and it seemed a pity it should not be good. Three elements went to design. First, the physical properties of the material; secondly, there was the tradition or history of man's mastery of it, and thirdly, the need which the product had to serve. The good designer got these three things thoroughly engrained in his mind, and the result was that his work looked as if it had grown. The road to artistic wisdom lay in external nature rather than in authority and tradition. The endless variety of beautiful lines, colors and contours to be found in the growth of vegetation, in animal forms and in the sweep of sea and land and heaven above and around us must ever remain the standards of beauty for man, and in the loving observation of these would be found the ultimate education for that seeing eye which was the final court of appeal in matters of taste.

A GOOD RED DIP.—One of the best red dips known consists of the following:—6 lbs. of red oxide of iron, 3 lbs of Cornwall stone, ¼ lbs. of borax, ½ lb. of barytes. Lynn sand can be used in the place of barytes, and scarlet red in the place of oxide of iron. In preparing the above, mix them well together, then calcine them in a pot or saggar. They can then be ground together into a slip. Take one quart of stain to ten of the clay slip, varying it according to the strength of the clay, to bring up the bright red. For large articles, paint the stain on with a brush when they are black hard.

ARCHITECTURAL DISGUISES.

Concealment of structural materials and forms is one of the characteristics of our modern architecture, says the *Building News*. We have passed from an age of imitation to one of disguises. Formerly it was the fashion to make stucco marble, and graining the natural figure of real wood. Even the groined stone vaults of the churches were represented by the plaster imitations, as in that of St. Luke's, Chelsea. Art apostacy could not have been carried further, for these imitations lost sight of the constructive in all the materials that were so represented or misrepresented. The jointing of stone work and vaulted masonry depended upon the whim of the stuccoist; there was a want of reality apparent which quite demoralized the art of masonry. To a like extent carpentry, and especially joinery, suffered from the enstoms of painting and graining everything, for good jointing and clean finish were impossible when woodwork was painted a stone color, or grained to imitate oak or mahogany.

But this era of misrepresenting constructive materials has passed away—let us hope for ever, and honesty of construction has taken its place.—For a brief period the reaction from imitation led to excesses, for we remember the time when naked brick and stone walls, and unpainted woodwork were looked upon as virtues, and when everything in the shape of casing was pronounced an abomination. Church roofs and wooden benches of the 13th century simplicity and skeleton organs divested of all casings were the order of the day. We have now recovered from these bursts of enthusiasm, and are settling down to rational doctrines in architecture, as we are in church and house building. We have begun to see the difference between mere imitation and clothing; that a covering is not necessarily bad architecture. Still, there are modes and rules to be observed. The increase of new materials and appliances has brought with it a new danger which the architect has to guard against, and to which we may briefly draw our readers' attention.

First, there is the inducement to cover a plain, inexpensive material with one of greater value in the same manner as common metals are electro-plated with silver and gold. Even the ancient Romans resorted to the practice of veneering their buildings with slabs of marble. Secondly, the desire to economise has encouraged the manufacture of materials for the purpose of encasing construction. The first motive, if it does not go so far as to deceive the eye, is reasonable. Take, for example, a wall-lining: if it represents by joints and masonry a stone wall, it is certainly dishonest; but if it is merely fixed to the surface in slab-like pieces, and does not pretend to be anything more than a surface incasement, we cannot find fault with such a mode of wall enrichment. A number of projecting piers or pilasters covered by a marble veneer would be misleading and wrong in design, but a flat, superficial mode of panelling would be quite legitimate. A plaster ceiling "jointed" to represent solid voussoirs and ribs is obviously wrong in principle, and plaster in such a position should be treated as plaster panels by painted or fresco decorations, and in no case show masonry jointing. A more legitimate motive to cover a structural material is to give it a more presentable or comfortable surface, as that of encasing a brick wall with plaster or an iron column with wood, and this motive power opens a very wide field for the use of all kinds of non-conducting and artistic surfaces. But in this application there is decidedly need for caution. There is the danger of sacrificing the real structure or material, as, for instance, in making the design for an iron column suitable for a wooden or a marble one; in short, of thinking of the encasing material rather than of the actual support. In this way the sin of imitation or misrepresentation is likely to be revived if architects are not on the alert. Let us take a few examples. Iron columns and stanchions are frequently used to support the upper walls of large banking premises. These are generally incased either in plaster or wood, and we have seen these casings made to agree with the wall or dado work by covering the iron column with panelled work, making them square or octagonal, instead of honestly treating the column as a support and arranging the casing independently of adjoining woodwork. We often see walls lined by materials which are designed or manufactured to ignore the idea of a wall lining. The panels, instead of being large and square, are in a profusion of small sizes, irregular in shape, set diamond wise, intended to display the joiner's art, or the fabric itself, whatever it may be. All this is contrary to art. Marble veneers, wood parquetry, glass, keramic decoration are all open to this objection. We found fault with stucco or plaster walls painted and jointed to represent marble: an almost similar objection would apply to a casing which ignored the walls and its piers.

Ceiling decoration, including in this description skylights, the incasing of girders, and other structural things, is a disguise which is often carried to an excess. The whole construction of the floor, or roof—whatever it may be—is so far disguised by plaster or papier-mâché decorations, that the design of the roof is lost sight of. The whole structure is changed. Is this architecture? Certainly not, if we accept the definitions. Is it architectural to introduce hugh plaster coves to flat roofs carried by beams or girders, so as to give the ceiling a semi-domical shape? Imagine a large room with a flat over it made to represent inside a vault of plaster. Yet this kind of construction is often met with. We see an ugly external skylight, so covered and shaped internally by decorative adjuncts as to totally alter its constructive form; or an iron girder transformed into a flat arch or incased in plaster several feet deep to give it the appearance of an entablature supported on end columns which carry nothing. These are every-day instances of how we disguise our large buildings, town halls, city banks, and residential blocks. We do not say these sorts of materials are inadmissible when they are made to incase timber or iron, so as to present an internal covering: but let it be done honestly, without going out of the way to falsify the invisible means of construction. We can understand, for example, the incasement of an iron column or a plate-iron girder by materials which present more suitable surfaces internally, such as plaster or papier mâché, or wood and keramic decoration; but there is a right and a wrong way of doing it, both in the application and mode of decoration.

The fashion of disguising structural features, and especially iron, is developing in several ways. Some time ago iron was boldly used in columns, roofs, and other structures, and the material was left untouched. Several applications of iron are to be met with. We have, for example, lately seen an iron staircase in which the strength and rigidity of wrought iron has been given in shape of strings and risers, which are covered with wood. The iron plate string shaped to the curve of stairs is sandwiched between wood strings, the outer one of mahogany, and the risers of iron riveted to the string have teak on the outside. The St. Pancras Iron Company have, we understand, carried out several of these staircases, one of which we described last week. There is no reason, artistic or otherwise, why strength and rigidity should not be given to these and like structures by the use of iron as a skeleton frame work. An iron frame economises space, and where curves are required, as in a wreathed staircase or in theatre-gallery construction, the value of iron is undoubted, and many of our threatres, such as the Alhambra and the Empire, have their galleries and dress circles constructed of iron imbeded in concrete. Disguises of this kind are legitimate and harmless enough if they do not assume too much, such as imitating stone or marble.

The consideration of economy in the employment of materials that take up little room and cost less than making a structure solid is sound as a principle, if only builders and architects knew what real economy was. They have often, however, confounded cheapness with it, and have encouraged the use of materials which are anything but economical in the long run, or have done what is quite as reprehensible—reduced the working strength of their iron girders and columns, and have made up their apparent size by using cheap substitutes as a covering.

All kinds of patented compositions have been introduced as concealments of structure of recent years. Wood has been manufactured into a variety of ways for wall and other linings; all manner of plastic materials have been used for similar purposes, even leather and paper and wood-fibre have been pressed and embossed into a variety of forms; Anaglypta, leather papers, and other like materials, have come largely into use in decorations, and we have substitutes for cement, stone, and marble—all of them excellent in their way—intended to cover, protect, or decorate our buildings. But, in the multitude of these inventions and appliances, there is a danger of disregarding solid, honest construction, and in sacrificing good design to superficiality, and artistic ornament to spurious and unmeaning repetition.

ELECTRIC KALSOMINING MACHINE.

ONE of the queerest applications of electricity at the World's Fair, says the *Western Electrician*, is the attachment of a motor to a machine that is doing a large share of the painting—or kalsomining, to be strictly correct—on the interiors of the great buildings. It was discovered some months ago that it would be very difficult, even with a small army of men, to do all the necessary painting by hand, and so C. Y. Turner, who is interested in the painting contract, devised an apparatus which, with the assistance of two men can apply as much kalsomine in a day as forty men with brushes. The painting machine consists essentially of an electric motor, a rotary pump, a barrel of kalsomine, a line of hose and a flat nozzel. The nozzel consists of a gas pipe about a foot long, pounded flat at one end so as to leave an opening about an inch across and wide enough to insert a sheet of card board. The pipe is attached to a long piece of rubber hose, the other end of which is dipped into a barrel of paint. A rotary pump run from a countershaft operated by an electric motor forces a current of air and particles of paint through the hose. The force of the air scatters the paint in a fine spray as it comes from the gas pipe. A painter simply seizes the gas pipe, holds it about eighteen inches from the surface he is decorating, the electric motor is turned on and the work is done. Mounting two men with this device upon a movable platform scaffolding, the work of a gang of men for a fortnight can be accomplished in one day. The motor used is of the Edison type, of five horse power capacity. The arrangement has been in successful operation for some time. The color used for the interior of the electricity building is a very delicate blue, and it is evolved out of several component parts. A deep Prussian blue is the pronounced color taken as the basis. Dutch pink, which is not pink at all, but rather a reddish yellow, is another component, and these two are tempered with white in the proportion of 360 pounds of whiting, four and one-half gallons of Prussian blue. All the great iron arches in the roof have been painted by brushes. Half a dozen men are still plying brushes above the galleries, but in other proportions of the building hose lines are playing on the woodwork. The effect of the things is very pleasing, and the work is now nearly completed.

SOME NOTES ON PEN DRAWING.

IN this age of the perfection of pictorial reproduction and of the multiplication of illustrated magazines, it is not surprising, writes Albert P. Willis in the *Architectural Era*, that architects along with other classes should endeavor to use these means of placing their work before the public. Looked at merely from a business point of view it introduces them, for better or worse, to a wider circle of critics than would ever see their products in stone or brick. This is perfectly legitimate and were the work well done nothing more need be said ; but some of it is as poor in execution as anything ever honored by the name of illustration. If architecture is a fine art, as every day we are coming more and more to believe it to be, its practitioners must be seen by other lights than through an atmosphere of plans, estimates and contracts. Their works must appeal to us as things of beauty, and their illustration in the press must be artistically presented as our knowledge and experience will permit. If architects deem it necessary or tempting to illustrate at all, surely such illustration should not do injustice to the building itself.

It is admitted that the purpose of a drawing should govern its production ; now as the purpose of a pen or wash drawing cannot be purely descriptive, plans and elevations could fill that office better. It must be pictorial ; it must endeavor to present a building in an attractive manner ; to give us a composition with the building as the central and striking feature.

DESIGN FOR A VILLAGE CHURCH.—GREGG & GREGG, ARCHITECTS, TORONTO.

Some architects, I fear, find themselves unable to do this, and perhaps, hand the work over to one of the 'T-square' trained office men, as incapable as themselves. Let us rejoice, however, that our best firms, in such a predicament, employ an artist or illustrator and with most exceellent results, as Blum's drawing of the Alcazar at St. Augustine, for instance, will prove.

If the architects want to do the work themselves they at least should become acquainted with the methods of well known illustrators. There is a score of artists in this country who in the last few years have had occasion to illustrate architecture, and while they know nothing about its technical features their numerous drawings in *Harper's*, *Scribner's* and *Century* bear testimony to the excellent work done. The means employed have been various, but none I think have given better results than pen and ink. For clean, sharp, crisp drawing and for the expression of detail it cannot be surpassed.

In looking over a list of pen draughtsmen whose works are worthy the study of the architectural student, the difficulty lies in selecting the few representative ones ; Pennell, Brennan, Blum, Cox, Gregg, Meeker, Fenn and some others claim recognition. They are all able men who well know the limitations of their art. Some of them are close students and large borrowers of the methods of the great Spaniards, Fortuny, Rico and Vierge, but that should not detract from their prestige.

Pennell's illustrations of the English cathedrals, which appeared in the *Century* in 1888-89, give him the first claim for consideration. The beauty of his drawings lies in the grace and economy of line, the exquisite expression of atmosphere, the large use of whites, the sparing and concentrated use of blacks Between his and Rico's work there is a striking similarity, making allowance of course for the difference produced by the brilliant sunlight of Spain and the cooler lights of England and America. He works mostly on Whatman's hot pressed or some paper with a slight grain. This, in the reproduction, gives a slightly broken line, very good for soft effects. Ordinarily he uses a Gillot's "Crow Quill," 659, which he claims is almost a living thing, so responsible is it, to the touch and so wide in its field. Occasionally, however, we find him using other and heavier pens, to suit the occasion. His lines are broad and open with little cross hatching. The forms are defined either by outline without shade or shade without outline ; only occasionally combining the two. The very scarcity of his blacks makes their occurrence extremely telling. Texture and local color are almost eliminated, and the general effect seems to be gotten by the juxtaposition of a great variety of grays. When he has occasion to use single outlines he is careful to break them frequently.

These, as nearly as can be formulated are Pennell's methods. At times he forsakes them to try new things ; occasionally we find him using lithographer's crayon to scumble in his shadows at other times he combines the pencil with the pen. But whatever the experiment, whatever the work, we will see the same masterly knowledge of drawing and chiaroscuro, the same patient toil over detail which yet does not obtrude itself. It may be interesting to know that Pennell seldom uses the camera, sketching directly from the building. Though we have been unable to print any of Pennell's works, through the kindness of the *American Architect* and the *Engineering Record* we are enabled to show drawings by two men, Gregg and Meeker, whose methods differ so radically from each other and from Pennell's as to be extremely interesting and instructive. The former is a jurist, if such a term may be applied to the art. He discards local color and texture, and seldom uses the outline without breaking it into dots, and never cross lines. The shade lines which are apt to be slightly wavy, by their direction give no clue to the inclination of the surface. Gregg has certain well defined effects in view, which he attains in the most direct manner at the expense of all else. His work is open and devoid of tricks, his results are soft and clear.

The second artist, Meeker, while working with more feeling for artistic effect, yet has not that singleness of purpose which characterizes Gregg in his work. The latter discards everything but mass and shadow, the former pays little attention to cast shadow, but devotes himself to the material of his walls, the stone jointing, etc. His darks are used rather to show windows, emphasize the carving and to indicate difference in color than to give the larger elements of the building their proper relief. The different materials used also make considerable difference in the result. Gregg uses an Esterbrook or Gillott pen, making a medium line, whose direction is studied. Meeker seems to use a "Crow Quill" on a perfectly smooth paper, which allows the pen to wander over it with perfect freedom. With him the

direction is of no consequence. Both men confine themselves more to one kind of pen than Pennell does. Meeker's work in the ensemble, though lacking the modelling of Gregg's, still has more snap and life, especially his grass and trees. The conflict of aims in his drawings is the result, I think, of the too frequent use of the photograph. There are other treatments with the pen, such as are used by Wilson Eyre or Kirby, but the work of the latter appeals to me more as outline drawing, as architectural suggestions or memoranda, than as finished drawings.

There is one Englishman, Herbert Railton, whose work may be studied with profit. His style is peculiar to himself. There is a sparkle about it which in the single drawing is charming, but, alas, when seen in the aggregate this very excess of glitter becomes monotonous. His frequent and unsystematic use of blacks, which he evidently put in with a toothpick or brush, and his spotty and broken lights, are in the mass unpleasing. The rapidity with which he works gives a peculiar hooked radiating character to his lines, and this stroke does yeoman service for walls old or new, surfaces smooth or rough, grass or trees. If the effect is not dark enough he does not hesitate to crossline, being careful to subordinate the second series of lines to the first, thus keeping a predominating tendency to the lines. In this I think he has the advantage over Pennell.

In these few remarks I have made no effort to go deeply into the subject of pen illustration. This has been so ably done by Pennell in his book on pen draughtsmen that it seems superfluous to attempt to do more.

WHAT IS A CONTRACT ?

A contract, says *Metal*, is a deliberate engagement between competent parties, upon a legal consideration, to do, or not to do, some act. In its widest sense it includes records and specialties, but the term is usually employed to designate only simple or parol contracts. By parol contracts it is to be understood, not only verbal and unwritten contracts, but all contracts not of record nor under seal. This is strictly the legal signification of the term contract, inasmuch as that reciprocity of consideration, and mutuality of agreement, which are necessary to constitute a parol agreement, are not requisite in obligations of record and in specialties.

Contracts are divided into three classes : first, contracts of record, such as judgments, recognizances and statutes staple ; second, specialties, which are contracts under seal, such as deeds and bonds ; third, simple contracts, or contracts by parol.

A parol contract, then, is any contract not of record, nor under seal, whether it be written or verbal. Certainly the facility of proof are all the advantages gained by reducing such an agreement to writing ; the liabilities of the respective parties are not changed. Every contract is founded upon the mutual agreement of the parties, and that agreement may be formally stated in words, or committed to writing, or it may be a legal inference, drawn from the circumstances of the case, in order to explain the situation, conduct and relations of the parties. When the agreement is formal, and stated either verbally or in writing, it is usually called an express contract. When the agreement is matter of inference and deduction, it is called an implied contract. Both species of contracts are, however, founded upon the actual agreement of the parties, and the only distinction between them is in regard to the mode of proof, and belongs to the law of evidence. In an implied contract, the law only supplies that which, although not stated, must be presumed to have been the agreement intended by the parties. The law always presumes such agreements to have been made, as justice and reason would dictate, and assists the parties to any transaction to an honest explanation of it. But a promise will not be implied, contravening the express declarations to the party charged, made at the time of the supposed agreement, unless such declarations be at variance with some legal duty, and then the law will imply a promise to perform that duty.

Wherever a party avails himself of the benefits of services done for him, although without his positive authority or request, the law supplies the formal words of contract and presumes him to have promised an adequate compensation. So also where a person engages to do any work or perform any service, he is understood to engage that he has sufficient skill and ability to fufil his contract, and also that he will use all the means necessary to accomplish it. So, also, if a man having a title to certain property silently permits another to deal with that property as his own, in all transactions between such person and others, acting in the confidence that the property belonged to him, the true owner would be bound.

Thus, if a man stand by and knowingly sees his own property sold and either encourages the sale or does not forbid it, the law implies a contract between him and the vendee, and accredits the actual seller as his agent ; and this rule obtains on the clear ground that if one of two innocent persons must suffer a loss, where one had misled the other, he who has been the cause of the loss ought to bear it. But in all cases, the circumstances must be such as to unequivocally imply a contract between the parties, and evidence may be given to rebut such a presumption. Nor is this rule restricted to cases where the true owner of property knowingly permits another to make sale of it, without interference or objection, but it extends also to cases where a party, being ignorant that he has any title, does or says anything in the premises which actually misleads the purchaser to his injury ; for however innocent he may be of a fraudulent intent, he ought to suffer the consequences of his own act, whatever loss or injury must accrue to one or the other party. Yet, if his mistake would not occasion absolute injury, or did not operate to deceive, he will not be bound thereby. So whenever there is a uniform usage in a particular trade the parties are presumed to have contracted in reference to such usage, unless it be expressly excluded by them, or unless it be inconsistent with the actual terms of their agreement. It must, however, be a general usage, or a universal custom which is brought home to the knowledge of the party, or it must be the special course or habit of dealing of one of the parties, recognized and assented to by the other, or no such presumption will arise. In such cases, the usage is understood to form a portion of the contract, and to exclude a rule of law inconsistent with it.

If, in a written contract, the words of recital or reference manifest a clear intention that the parties shall do certain acts not expressly stipulated, the courts have therefrom inferred a covenant to do such acts and have sustained actions of covenant for their non-performance, in like manner as if the instrument had contained express covenants to perform them.

HOUSE MOVING.

THE *Scientific American* says :—The ferry-house located at the Brooklan terminus of the thirty-ninth street ferry, between the Battery in New York and South Brooklyn, is a brick structure 52 by 110 feet. This building was located at the foot of Thirty-ninth street. The Brooklyn City Railroad Company required increased facilities in that part of the city, and in consequence of this the ferry-house was removed from its original site 150 feet westward and 25 feet northward, and when the job is completed the building will stand 17 inches lower than it stood on the old site. This work was done in about one month, without injury to the walls, and at much less expense than would have been involved in tearing down and rebuilding.

The building was placed on a rigid framework and its walls were shored and braced by tie rods and cross timbers, and it was moved on ways consisting of a framework of heavy timbers provided with diagonal guides which caused the building to move sidewise as well as endwise, the frame upon which the building rested being provided with shoes sliding diagonal guides. The abutments against which the moving screws rested were heavy timbers secured to the ways by means of chains. After the screws which abut upon the timbers had been run out their full length, they were returned to their original positions and the timbers moved forward and again made fast, when the operation was repeated.

This job was done by B. C. Miller & Sons, of Brooklyn, N. Y., who moved the Brighton Beach Hotel bodily in 1889, after the damaging encroachment of the sea on the beach. The building was 465 feet long and 150 feet deep, three storeys high and weighed 5,000 tons. It was moved 239 feet back of its original position upon 112 platform cars by means of six locomotives.

The appointment of a building inspector is being advocated by one of the Kingston aldermen, who states that at present buildings are sometimes erected of fragile material and weak construction.

STRENGTH OF CONCRETE.

A PAPER recently read before the Society of Architects, London, by Mr. H. W. Chubb referred to the use of concrete as a material in building fireproof structures. The specimens of concrete which Mr. Chubb mentioned as having been tested by Mr. J. J. Webster, M. I. C. E., had been specially prepared. The following table shows their composition, together with the results which were obtained:

Nature and Proportions of Materials in Concrete Briquettes.	Average weight per cubic foot.	Breaking weight per square inch at 60 deg. Fair.	Breaking weight per-square inch after being heated and quenched.	Average loss per cent. of original strength after heating and quenching
	lbs.	lbs.	lbs.	per cent.
Neat Portland cement	124.6	554.6	117.2	66.8
1 part cement, 1 part sand	126.9	448.0	93.0	80.0
1 part cement, 3 parts sand	111.2	100.8	18.7	81.4
1 part cement, 5 parts sand	109.7	74.6	15.0	79.8
1 part cement, 4 parts iron furnace slag	163.08	108.1	23.06	69.3
1 part cement, 1 part pumice stone	64.8	94.58	38.3	59.5
1 part cement, 4 parts broken fire-brick	95.04	84.4	30.5	50.9
1 part cement, 4 parts coke breeze	71.65	69.9	39.06	57.1
1 part plaster of Paris, 4 parts broken fire-brick	89.6	66.8	10.3	75.6
1 part plaster of Paris, 4 parts pumice stone	55.6	57.4	3.4	94.7
1 part plaster of Paris, 2 parts furnace slag	148.0	223.3	6.9	96.8
1 part plaster of Paris, 2 parts broken fire-brick	106.9	165.5	15.7	90.0

DOORWAYS.

A VERY important feature of the house in more than one respect is the doorway. It is in fact a most prominent part of the structure, says *Trefoil*, and only too many are the possibilities between making it a work of art like the masterpieces of Ghiberti on the Baptistery in Florence, or leaving it a mere aperture in a monotonous expanse of wall, which reminds us forcibly of the hole in the fence or the crude entrance of a tent, from which the door doubtless took its origin.

In many instances the entire effect of an otherwise pleasing structure is hopelessly marred by the treatment accorded the doorway, and more than one facade is reduced to the commonplace by the utter neglect or the architectural decoration to which the door, if any part of the building, is most legitimately entitled. To the eye, the doorway and the roof line are the critical points in a building, and the good treatment of either will do much toward remedying the defects of a poor design.

It will hardly do, however, to blame the architects for the stagnation of public taste for half a century in regard to architecturally meritorious doorways. In this country, particularly among a class of owners that, above all others, might have done so much to bring about the much needed revolution of an architectural sense, art has been subjected to rules and restrictions that might aptly apply to card etiquette, but the effect of which upon architecture can only be deplored. When a doorway essentially ugly has come to be considered the only proper thing by a vast number of people in the community, the era of the studied commonplace can be said to have reached the climax.

This was pre-eminently the case some twenty years ago. Our revolutionary forefathers in this respect had better taste; they followed the classical ideals they had with a zeal that gave us, if not a new style, at least a strong impulse toward something good. The decadence was, however, rapid. In 1850 doorways were mere holes in the wall, and thereafter followed a period of barren ugliness and dull respectability, an era of unredeemed bad taste, from which the newer departures in architecture, and its more general appreciation, are beginning to save us.

DECORATIONS AND FURNITURE

FLOWER DECORATION.

DECORATION by means of natural flowers has from time immemorial been recognized as the most beautiful and effective method it is possible to conceive, the one and only disadvantage it possesses being its necessarily temporary character. It is this feeling that lead to the introduction of floral design cut in solid materials, of which we have such exquisite examples in the architecture of the thirteenth century. But all attempts at live flower decoration heretofore carried out appears to be eclipsed and thrown into the shade by the display in the Assembly Hall of the World's Fair upon the occasion of its formal opening by the President of the United States. A model of the Washington capitol made of *white flowers* was the central feature, the grounds in which the building stands being represented by real plants in miniature. The stage of the hall was banked up with palms and cut flowers while the head stairway was covered with a drapery of white and gold, festooned with smilax and tiny lamps. Pillars were traceried with smilax and flowers, while overhead canopies of white and gold hung with flags completed the gorgeous and tasteful scene. It is said that $10,000 was expended in this decoration of an hour.

Says "Goth" in the *Building News*: An art-critic complains of our modern stained glass. Greatly as we have progressed, there is yet a vast gulf between the effect of some old glass and that produced to-day. It may be that, like wine, stained glass improves with age: on many tints there can be no doubt that time has a mellowing effect. The quality that always seems to me to be wanting nowadays is the sparkle and scintillation of old glass such as we find in some of the Continental cathedrals. I suppose that the real secret of the matter is that we cannot get away from the idea that a stained-glass window is, and should be, a picture; whereas, considered as a decorative feature, it should be subordinate to the architecture and contribute to the general effect. Then there are two schools—on the one hand the advocates for dark effects and heavy coloring in broad masses, and on the other the more delicate style in which light and light tints play an important part, and the color is concentrated into little points with jewel-like effect. Considering the technical difficulties of the art, there is no need to despair, for, relatively, it has advanced as much as other handicrafts.

USEFUL HINTS.

A correspondent of the London *Ironmonger* furnishes a recipe which is easily tried and probably efficacious. He writes as follows: People often want to know how the steaming of windows can be obviated. I am told it is done in these parts with a solution of glycerine. Fifty-five grammes (about 2 oz.) of glycerine dissolved in one litre of diluted alcohol (about two-thirds alcohol and one-third water). After this solution has become quite clear moisten linen or leather with it and rub the window on the inside. It keeps the glass clear from freezing and steaming.

RESISTANCE OF MASONRY ARCHES.—The Austrian Society of Engineers and Architects is now engaged in a series of very important experiments on the resistance of masonry arches. Sufficient is now known of the strength and elasticity of stone and cements, says *Engineering*, London, to render the theory of the elastic arch applicable to masonry arches which have been and still are designed purely by empiricism, so that in many cases very little is known as to the actual stresses carried by the structures, and there is no doubt that the factor of safety is in many cases excessive. The experiments to be carried out will afford data as to the permissible working stresses, and the design and arches will therefore be simplified. One group of experiments will be devoted to researches of the elastic and resistant properties of the materials to be used in constructing the arches to be experimented on

DURABILITY OF TERRA COTTA.—During the discussion following the reading of certain papers on terra cotta before the Royal Institute of British Architects Sir Henry Doulton said: "As to its durability, I may perhaps mention two examples which occur to me as within my own observation. The figure of Britannia on the top of the Exchange at Liverpool was made a hundred years ago at Lambeth, and also the figure of St. John Crosby, which was made, when I was a little boy, at Lambeth. These, especially the figure of Brittania, though exposed to adverse influences, are as perfect to-day as on that of their erection. There happened to be two large statues on the triangular piece of ground opposite St. Thomas Hospital, brought here recently, also made at Lambeth, which are ninety-six years old, and which have been quite untouched by time. There is, of course, terra cotta and terra cotta; but there is no reason why terra cotta should not be absolutely imperishable.

MANUFACTURES AND MATERIALS

QUALITY OF ROOFING SLATES.

THE following are the general conclusions reached as the result of a series of tests of roofing slates, as given by Mr. Mansfield Merriam at the September, 1892, meeting of the American Society of Civil Engineers:

1. Slates containing soft ribbons are, by common consent, of an inferior quality, and should not be used in good work.
2. The soft roofing slates weigh about 173 pounds per cubic foot, and the best qualities have a modulus of rupture of from 7,000 to 10,000 pounds per square inch.
3. The stronger the slate, the greater is its toughness and softness, and the less is its porosity and corrodibility.
4. Softness, or liability to abrasion, does not indicate inferior roofing slate, but on the contrary it is an indication of strength and good weathering qualities.
5. The strongest slate stands highest in weathering qualities, so that a flexural test affords an excellent index of all its properties, particularly if the ultimate deflection and the manner of rupture be noted.
6. The strongest and best slate has the highest percentage of silicates of iron and aluminum, but is not necessarily the lowest in carbonates of lime and magnesia.
7. Chemical anaylses give only imperfect conclusions regarding the weathering qualities of slate, and they do not satisfactorily explain the physical properties.
8. Architects and engineers who write specifications for roofing slate will probably obtain a more satisfactory quality if they insert requirements for a flexural test to be made on several specimens picked at random out of each lot.
9. Although the field of this investigation is probably not sufficiently extended to fully warrant the recommendation, it is suggested that such specifications should require roofing slates to have a modulus of rupture, as determined by the flexural test, greater than 7,000 pounds per square inch.

THE KENT FREESTONE QUARRY.

The Moncton, N. B., *Times* states that the formation of a joint stock company is in contemplation to develop the Kent freestone quarry situated on the Moncton and Buctouche railroad. This quarry, opened a few years ago, consists of 30 acres, on the bank of the Coeagne river. The depth of stone to the level of water in the river where the quarry is now being worked is 60 feet, and further up the stream the quarry shows a solid body of stone 125 feet deep. Lack of capital has up to the present hindered the proper development of this quarry, as well as some others in the same province.

The capital stock of the Gurney Foundry Co., Toronto, has been increased from $40,000 to $350,000.

The business of the Toronto Furance Co. will in future be carried on by the Toronto Furnace and Cremating Co., which has lately been incorporated with a capital stock of $40,000.

The Steel Clad Bath and Metal Co., of Toronto, who a year or so ago established a factory for the manufacture of the specialties at Detroit, Mich., have lately shipped to England the necessary plant for a factory which it has been decided to establish there. This is certainly an evidence of commendable enterprise.

CREDIT VALLEY BROWN STONE
From Carroll & Vick's No. 6 Quarry, Credit Forks, Ont.

SANDSTONE, fine grained, reddish brown. Contains quartz, and a little felspar and mica. The stone is in beds of four feet and under, and can be handled in pieces up to five tons. Quarry 300 yards from Railway.

Specimen.	Section under Pressure	Height.	Crushing Load.	Crushing Stress per sq. in.	Average Crushing Stress per Square Inch
	Ins.	Ins.	Pds.	Pds.	Pds.
A	.....	.....	.....	.....	
B	2 7/8 × 3	2 7/8	131,000	15,188	
C	2 1/16 × 3	2 7/8	130,000	14,751	
D	3 × 3	2 7/8	133,000	14,777	14,905

14,905 pounds is the average crushing strength per square inch of our Credit Valley Brown Stone.
The highest standard of test attained by any pure Sandstone in America.

IN confirmation of the facts above stated, we have pleasure in directing your attention to the accompanying table, showing the result of the test of our stone, in connection with the series of tests of building stones conducted in 1892 at the School of Practical Science, Toronto, under the direction of a committee of the Ontario Association of Architects.

By referring to the results of the tests above mentioned, it will be seen that the average crushing stress of the majority of Canadian and American sandstones is far below that of ours, the difference in our favor ranging from 75 to 50 per cent.

The Credit Valley Brown Stone, owing to its modest tone, harmonizes beautifully with red or cream colored brick.

It has been reported that there is difficulty in obtaining Credit Valley Brown Stone. To correct this mistaken notion, we wish to state to architects and the public that we have 40,000 cubic feet of stone ready to ship on the shortest notice, which can be followed up with an unlimited supply. Last year we made extensive additions to our plant and opened up new quarries and mines, and will supply promptly all orders given to us or our agents.

USEFUL HINTS.

BOARD MEASUREMENTS.—Boards are sold by superficial measurement, at so much per foot of an inch or less in thickness; adding one-fourth to the price for each quarter of an inch thickness over an inch. It sometimes happens that a board is tapering, being wider at one end than the other. When this is the case (if it be a true taper), add the width of both ends together, and half their sum will express the average width of the board. Again, if the board does not taper regularly, take the following course to find its area:

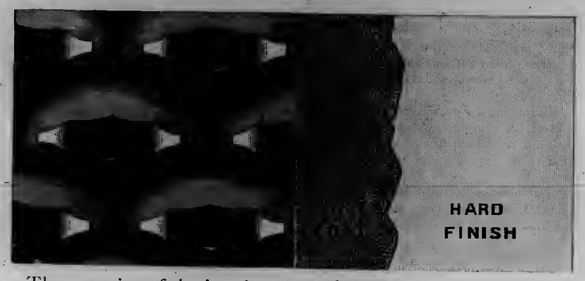
1. Measure the widths at several places equidistant.

2. Add together the different breadths, and half the two extremes.

3. Multiply this sum by the straight side of the board and divide the product by the number of parts into which the board was divided. It is usual in measuring rough lumber, to pay no attention to fractions of an inch in the width of the stuff. If the fraction is more than half an inch it is counted as an inch; if less than half an inch it is not counted. Thus, a board 10⅝ inches wide would be measured as 11 inches wide; if only 10⅜ inches wide the board will pass only as 10 inches.—*National Builder.*

PAINTS AND SHINGLES.—The *Timberman* very wisely remarks that it has always seemed singular that in the use of paint to preserve wood exposed to the weather, the fact that a shingle roof was omitted from the catalogue was invariably the rule. This idea of oversight was one of the things in which custom becomes habit, and because every one else did so, all the rest followed suit. It is safe to presume that the custom of leaving the shingle roof unpainted originated in its angular form being less exposed to the after effects of rain and snow. A little thought will show the folly of such a conclusion when remembering the frail nature of a shingle and the slight fastening it has. If paint would be useful to any weather exposed surface it would certainly be so on the roof. The fact goes without telling, and in the present style of suburban residences, the roof receives its share of paint along with the rest of the building, thus at once combining the useful with the beautiful. It is certainly singular that painting of roofs has not always prevailed, and it adds much to the finish and character of the building to see the roof painted. When the thin, slender nature of the shingle is taken into consideration, it will be plain to every one that sun cracks will easily go through the shingle, and to that extent render it worthless. The only way to overcome this is to paint and always keep the shingles painted.

Hayes' Patent Steel Lath



The tenacity of the bond and other features are unequalled.

Now being used in the "Grand Seminaire," Montreal.

CANADIAN ARCHITECT AND BUILDER.

VOL. VI.—No. VII. JULY, 1893 PRICE 20 CENTS $2.00 PER YEAR.

THE
CANADIAN ARCHITECT AND BUILDER,
A Monthly Journal of Modern Constructive Methods,
(With a Weekly Intermediate Edition—The CANADIAN CONTRACT RECORD),
PUBLISHED ON THE THIRD THURSDAY IN EACH MONTH IN THE INTEREST OF
ARCHITECTS, CIVIL AND SANITARY ENGINEERS, PLUMBERS, DECORATORS, BUILDERS, CONTRACTORS, AND MANUFACTURERS OF AND DEALERS IN BUILDING MATERIALS AND APPLIANCES.
C. H. MORTIMER, Publisher,
Confederation Life Building, - TORONTO, CANADA.
Telephone 2362.
64 TEMPLE BUILDING, - MONTREAL.
Bell Telephone 2299.

SUBSCRIPTIONS.

The CANADIAN ARCHITECT AND BUILDER will be mailed to any address in Canada or the United States for $2.00 per year. The price to subscribers in foreign countries, is $2.50. Subscriptions are payable in advance. The paper will be discontinued at expiration of term paid for, if so stipulated by the subscriber; but where no such understanding exists, will be continued until instructions to discontinue are received and all arrearages paid.

ADVERTISEMENTS.

Prices for advertising sent promptly on application. Orders for advertising should reach the office of publication not later than the 12th day of the month, and changes of advertisements not later than the 5th day of the month.

EDITOR'S ANNOUNCEMENTS.

Contributions of technical value to the persons in whose interests this journal is published, are cordially invited. Subscribers are also requested to forward newspaper clippings or written items of interest from their respective localities.

The "Canadian Architect and Builder" is the official paper of the Architectural Associations of Ontario and Quebec.

The publisher desires to ensure the regular and prompt delivery of this Journal to every subscriber, and requests that any cause of complaint in this particular be reported at once to the office of publication. Subscribers who may change their address should also give prompt notice of same, and in doing so, should give both the old and new address.

THERE has just been published by the direction of the General Assembly of the Presbyterian Church in Canada, a pamphlet of nearly forty pages containing illustrations accompanied by brief descriptions of designs suitable for country, village and town churches. Most of the designs are reproductions of drawings submitted in the recent Presbyterian church competition. Although they cannot all be declared to be satisfactory examples of church design, the excellence of some is such as to encourage the hope that they will in a measure serve the object the church had in view in their publication, viz., improvement in the design of rural churches. The authorities of the Presbyterian church deserve commendation for the attempt they have made to improve our church architecture. It is to be hoped the result of their first modest effort will prove so satisfactory that at some future time they will feel encouraged to carry their purpose a step farther.

THE ingenuity of the impecunious and dishonest contractor is truly wonderful, and when aided by that of an unscrupulous lawyer, is well nigh certain to succeed in defrauding persons unaccustomed to doing business in other than a straightforward manner. A contractor and lawyer of this description have been practising of late in Toronto, and have succeeded in defrauding a number of supply firms and sub-contractors. The lawyer writes a letter stating that the contractor is about to secure through him a loan, and that he will control its distribution. The impression is conveyed that the lawyer will assume responsibility for the payment out of the loan of claims for material and labor required by the contractor in the carrying out of his contract. The letter is, however, so skilfully worded that while it has in several instances obtained for the contractor the material and help he required, the supply firms and sub-contractors who subsequently brought suit against the lawyer were unable to recover their claims. It is hoped that this *expose* may assist in putting a check on such crooked practices.

THE difficulty of securing the title to the land required for the proposed union railroad depot at Toronto, which has been the means of delaying for nearly a year construction on the building, at last appears to have been overcome, and the work is to be proceeded with at once. In the present inactive condition of building enterprise it is satisfactory to learn that this important undertaking, which will absorb both labor and material to a considerable extent, is to go forward during the present season. In this connection we must express our regret that apparently no advantage is to be taken of the favorable circumstances at present existing for permanently improving the appearance of the water front. The shabby old wooden structures which occupied a portion of the site required for the new depot, instead of being torn down and forever banished from sight, have been permitted to be removed out to the line of the new street which it is proposed to construct as a promenade at the water side. The city authorities should determine to get rid of these and as many as possible of the other old buildings which for years have disfigured the city front and falsely impressed strangers visiting it for the first time by boat or train. Has the idea of a small park on the water front been abandoned? We trust not. The opportunity now exists for establishing such a park or garden, which would do much to make the city front attractive and afford a pleasant resting place for persons having to wait for boats or trains, as well as those who would wish occasionally to enjoy a half hour beside the water without being obliged to spend effort, time and money to go across to island park.

WITH many others we indulged the hope that the disgraceful revelations brought to light a couple of years ago of bribery and fraud on the part of government officials and contractors for public works, would suffice to purify the methods of these classes of persons in the future. Unfortunately in this hope we have been disappointed by the evidence which has lately been given before the Commission appointed by the Government to investigate the expenditures and circumstances connected with the erection of the new railway bridge across the Lachine canal at Montreal. The investigation was ordered when the fact became known that the estimated cost of the work,

which was $250,000, had been exceeded by $200,000. The investigation has shown that the work was not let by contract, but was done by day labor under the supervision of government officials. It would be instructive to learn why the usual custom of letting such work by contract was departed from in this instance, and under whose authority the departure was made. It is also pertinent to enquire why, having decided to do the work by day labor, the government superintendent did not hire direct the mechanics, laborers and teams required, instead of making a contract with a third party to supply them at prices which enabled him to pocket a substantial commission on the transaction. The thing has the appearance of having been worked in this way for the deliberate purpose of enriching certain individuals at the expense of the government and the country. The evidence given before the investigating Commission strongly supports this view. The testimony is that double the number of men, horses, and in some cases material, were provided and paid for than were required, that the prices paid for both work and material were largely in excess of the market value, and that material was paid for by the government which was diverted to the use of private individuals connected with the work. In short, as we have said, there appears to have been an organized and successful effort on the part of everybody to rob the government, as was illustrated by the remark of a laborer who, when some one suggested that less men were required to do the work, replied "Mind your own business—we're working for the government." It is to be hoped that a severe example will be made of persons who may be proved guilty of having conspired to squander the public funds for their own benefit and that of their friends. The boodling propensity which seems to have obtained such deep root must, if possible, be stamped out.

LEAD water pipes that are used on streets occupied by electric railways who use the rail for a ground and return, are found in various places to be seriously affected by the eating away of the outside of the pipe by electrolytic action. In the city of Hamilton the water department have been compelled to renew the service pipes in quite a few places, the worst affected seeming to be in close proximity to the power house. It would perhaps be quite a difficult matter to advance a proper theory for this result. It is perhaps caused by the pipe being laid in a particularly dry sandy soil, and by the return current in its effort to reach a good ground finding such ground by way of these lead pipes to the water mains in preference to forcing its way to a wet spot in the ground through dry sand or perhaps rock. That it should occur in the immediate vicinity of the power house is more difficult to account for, unless it be that the rail connections on the ground plate at that end offer a greater resistance to the passing of the current than does the intervening earth between the rails and these numerous water service pipes. In the case of Hamilton the water mains are several feet higher than the level of the bay and the streets all dip at a great angle to the bay, forming thereby a water shed that must result in a somewhat dry sub-soil. That the pipes are eaten away as the result of the current going to ground through them there can be no doubt, and that this action is purely an oxidization of the metal through the electrolytic action is reasonably certain. To remedy the trouble we think will be quite a difficult matter, but as experiments in that direction will no doubt be the order of the day, we would suggest the following as worthy of consideration and trial: Wrap the pipe with a covering of tarred (pine tar) hemp about half an inch thick before burying it; give the outside of the pipe a thick coat (or two or three coats) of a good, hard, but elastic japan, which has been well dried in an oven; let the outside of the pipe be enamelled with an elastic enamel the same as is now being used on the inside of some lead water pipes; surround the pipe by a square box some three or four inches in internal diameter, thereby allowing an air space as an insulator; last but not least, see that the rails are well grounded, bearing in mind the fact that a hole dug some six or seven feet in the ground and a large piece of an oil boiler stuck in with a number 4 galvanized iron connection to the rail is simply no ground at all in a sandy soil, and would not be much better in a pool of water. For the carrying of heavy currents such as are used in street railway work, a good ground should consist of at least 100 square feet of exposed metallic surface, preferably copper, covered on its two sides with at least one foot in thickness of fine gas coke and buried in decidedly moist earth, and connected to each rail by a No. 0000 copper wire well rivetted and sweated on. With such a ground every quarter of a mile, and good and sufficient bonds between the rails we predict that the eating away of lead water pipes would soon be a thing of the past.

CANADIAN PRESSED BRICK IN THE UNITED STATES.

A CANADIAN manufacturer of pressed brick informs us that he has an order from Boffalo for 200,000 bricks, and that other Canadian firms in the same line are shipping quite extensively to eastern American cities. When asked what gives rise to the preference for Canadian brick, he replied that it is mainly their superiority and uniformity of color. "We are able," he said, "to manufacture two hundred thousand bricks in which exactly the same shade of color will be maintained. The American manufacturers, owing I presume to the nature of the material at their disposal, do not appear to be able to succeed thus in securing uniformity of tone. Hence we find Americans who, in order to secure superior results, are willing to pay the duty on Canadian bricks."

ILLUSTRATIONS.

COMPETITIVE DESIGN FOR PROPOSED NEW GOVERNMENT BUILDINGS AT VICTORIA, B. C.—MESSRS. DICK & WICKSON, ARCHITECTS, TORONTO.

BANK OF HAMILTON, WINGHAM, ONT.—MR. D. B. DICK, ARCHITECT, TORONTO.

MONTREAL.

(Correspondence of the CANADIAN ARCHITECT AND BUILDER.)

Sir William Dawson, who for nearly forty years has discharged with distinguished ability the duties of President of McGill University, has retired. The weight of advancing years demanded that he should lay down the activities associated with the position. Sir William Dawson has commanded world-wide recognition as a scientist and educator, and has had conferred upon him many marks of distinction by learned societies, including the presidency of both the British and American Associations for the Advancement of Science. His successor to the Presidency of McGill has not yet been chosen.

There is a desire expressed by some of the aldermen that the city should discard the contract system and carry out municipal works by day labor under the supervision of the city surveyor and his assistants. By this means they hope to save the contractor's profits. In theory the thing seems easy of accomplishment, but it has worked out differently in practice in more than one city where it has been tried. It opens the door to jobbery, and for some reason or other the work costs more than when done by contract. Workmen in the employ of the city apparently do not feel called upon to put forth their best efforts.

It is reported that a large hotel is to be erected at the corner of Peel and St. Catherine streets, on the site of Erskine church, and that Mr. Townsend, architect, of New York, has been employed to prepare the plans. Dr. Dugald Graham's name is mentioned as being one of the leading projectors of the enterprise.

The formal opening of the new Board of Trade building has been postponed until September. The occasion promises to be one of much interest.

The Dominion Bridge Company has re-elected the following officers: Mr. James Ross, president; Mr. James P. Dawes, vice-president; Messrs. R. B. Angus, Duncan McIntyre, T. G. Holt, James Cooper and P. Donaldson, directors.

On the 13th of June there was sold at the Fraser Hall, a most interesting and valuable collection of antiquities and objects of art, the property of Mr. E. Collonna, architect, of this city.

About twenty-five models have been submitted in the competition for a memorial statue to the late Sir John A. Macdonald. These models have been open to inspection by the subscribers to the fund, prior to a choice being made by the Committee.

Owing to delay in completing the new additions, the formal opening of the art gallery will not take place until the autumn.

WINNIPEG.

(Correspondence of the CANADIAN ARCHITECT AND BUILDER.)

Mr. Geo. Browne, architect, of this city, has designed a new building to be erected for the congregation of Westminster church at the corner of Notre Dame and Charlotte streets. The structure will cost about $25,000, and will be constructed of white brick with Selkirk stone trimmings. The seating capacity will be upwards of 900. The auditorium is 65 feet square, with inclined floor and seats arranged in semi-circular form. There will be towers at three corners of the building and an octagonal bay on Notre Dame street.

Tenders have been invited for the erection of a new church for the congregation of St. Paul's, at Regina, to cost $20,000.

Mr. Hugh McGowan, architect, this city, has designed and commenced the erection of a new school building at Gretna, Man.

The corner stone of a new Methodist church at Boissevain, was laid with appropriate ceremony June 19th.

Tenders have been received by the Minister of Public Works for the heating of the new Court House building.

The Salvation Army is preparing to erect a building to serve as headquarters in this city.

A large number of small residences, ranging in cost from $500 to $2,000 are being erected here this season.

The Mason Contractors' Association and the Carpenters and Builders' Association, of this city, have recently amalgamated under the name of the Builders' Association of the city of Winnipeg. The move is without doubt a good one.

It is estimated that the total expenditure on buildings in this city during the present year will exceed that of 1892 by three quarters of a million dollars.

LONDON.

(Correspondence of the CANADIAN ARCHITECT AND BUILDER.)

In London this season there is an immense amount of building to be done, but so few good builders that they are busily employed, and tenders for new work are fully 30 per cent. higher than ordinarily. The result is already apparent, there are numerous prospective new residences which have already been dropped on account of the great cost, and others are sure to follow, especially if the fact of the change becomes generally known. I think it advisable to make these facts known in the hope that possibly some good brickworkers and carpenters in Toronto may be encouraged to figure on work here. If, as I am given to understand, building is not brisk in Toronto, there must be many contractors to whom the information would be beneficial. If building continues to be abandoned here for the reasons given above, contractors here will lose, and can afford to welcome outsiders. Recently two or three prominent firms here have given up business, so that there seems to be an unusually good opening for some one competent to manage a builder's business. The cause of giving up was death in both cases.

THE LATE JOHN. A. WILLS.

IT becomes our painful duty to chronicle the unexpected death on the 16th of June, of Mr. John A. Wills, Chief Engineer at the Toronto Custom House, and Chairman of the Board of Management of the Toronto Technical School. Mr. Wills, who was in his 48th year, was possessed of a naturally strong physical organization, and until the last two years enjoyed the best of health. Of late he was a sufferer from Bright's disease, and early last spring passed through a severe illness which several times threatened to have a fatal ending. Greatly to the comfort of his family and many friends, what seemed to be a marked improvement in his condition manifested itself a few weeks ago; he gained strength rapidly and was able to go down town. But a few hours previous to his death he drove around town with a friend who was on a visit to Toronto. After returning from the drive he lay down to sleep—which proved to be the sleep of death—for he passed quietly away a few hours later without having regained consciousness.

The deceased was a native of Ottawa, in which locality his parents were among the first settlers. After graduating from college, he entered as an apprentice the machine shops of Messrs. E. & C. E. Gilbert, at Montreal, who at that time were the principal manufacturers in Canada of marine engines. On completing his apprenticeship he went to the New England States, where he spent several years.

On his return to Canada he received the appointment of Chief Engineer of the Dominion Parliament Buildings, which position he held for three or four years, when at his own request he was transferred to Toronto and assumed the duties of the position which he occupied at the time of his death and for seventeen years previously. He took an active interest in the subject of technical education, and upon the organization of the Toronto Technical School was elected to the Board of Management and at the commencement of the present year was called to preside.

His cheerful, sympathetic disposition made for him a multitude of friends, to whom his sudden death is the subject of profound regret.

THE LATE JOHN A. WILLS,
Chairman of the Toronto Technical School Board.

TORONTO BUILDERS' EXCHANGE.

THE second annual excursion and pic-nic under the auspices of the Exchange, took place at Wilson Park, N. Y., on Wednesday, the 28th of June. The new and comfortable steamer, "Garden City," carried the pleasure seekers across the lake in less than three hours, and the water being smooth the time spent on the water was greatly enjoyed by all.

About two hundred members and friends of the Exchange participated in the outing. Business engagements prevented the attendance of some, while the threatening aspect of the weather in the early part of the day and the nearness of Dominion Day militated against a larger attendance. On the whole, however, the Exchange are to be congratulated on the success and enjoyment which marked the occasion, and which it is hoped will encourage them to maintain the annual excursion and pic-nic during many future years.

The steamer made two trips, leaving Toronto at 8 a.m. and 2 p.m. Fortunately the sky which in the morning was overcast with heavy clounds, gradually cleared as the sun's bright rays forced their way through and smiled graciously down upon the pleasure-seekers.

The voyage was much shortened and its enjoyment enhanced by the humorous character impersonations of Prof. Stuart and the charming music discoursed by Burton's orchestra. These also entertained the company in the pavilion after the arrival at the park, as well as on the return trip.

One of the principal events of the day was the baseball match, the rival teams representing respectively the builders and supply men. The builders' nine, which was captained by Mr. T. Cannon, was composed as follows: Messrs. T. Cannon, Benjamin Brick, Harry Martin, John Hanrahan, Eli Wickett, Jas. Crang, jr., E. B. Aaeworthy, Jethro Crang, Wm. Rowe.

The supply men were captained by Mr. John Maloney, their nine being composed of Messrs. Maloney, W. Whillans, B. McKenny, R. Elliot, W. Dickey, B. Anderson, L. Robertson, —. Mowat, W. Hollyman.

It was agreed that the playing should last for two hours. At the end of that period the supply men had scored 24 runs, while the builders had gained but 12. The game was a most interesting one and the playing on both sides very creditable, notwithstanding that the score from a professional standpoint might be regarded as a trifle large.

An interesting program of sports was also provided for the children, with suitable prizes for the winners. These special features and the excellent boating facilities served to pleasantly pass the time at the company's disposal. The only regret which we heard expressed was that, in view of the fishing possibilities, Mr. David Williams should have neglected to take with him a hook and line. It was a case of "what things one sees when he hasn't a gun."

The thanks of all who participated in this pleasant outing are due to the following gentlemen who composed the Committee of Management: Messrs. Thos. Cannon, chairman; David Williams, treasurer; John Phillips, secretary; John Maloney, Benjamin Brick, Harry Martin, M. Murphy, W. Williams, Joseph Brown, John Barnard and John Aldridge.

CANADIAN ASSOCIATION OF BUILDERS.

At a recent meeting of the Exchange, the subject of endeavoring to bring about the organization of a provincial or Dominion Association of Master Builders was discussed. While it was felt that the present, perhaps, owing to the prevailing depression, might not be the most favorable time to attempt the organization of such an Association, yet it was thought that the idea might to some extent be worked up. The Secretary was accordingly instructed to communicate with the Secretaries of the Builders' Exchanges in Hamilton, London, St. Thomas and Ottawa for the purpose of getting an expression of opinion on the subject. The advantages of such an organization have more than once been referred to in these columns, and we hope in the near future to see the proposal assume tangible form.

LEGAL DECISIONS.

AN ARCHITECT AND DEFECTIVE DRAINS.—We learn from the *British Architect* that in the Queen's Bench Division the other day, before Justices Mathew and Wright, the case of Levenberg *v.* Wykes came on for hearing. It was an appeal by the defendant, an architect, from the judgment of the County Court Judge at Birmingham after the finding of a jury. The defendant was architect of some houses built in Portland Road, Edgbaston, in 1878, and plaintiff's case was in that year, when there was a nuisance on the premises and the drains were opened, it was found that they had not been constructed in accordance with the plans deposited with the local authority. An action was therefore brought against the defendant for fraudulently representing that they had been so constructed, and the jury found a verdict for the plaintiff. Mr. Hugo Young, for defendant, now contended that there was no evidence on which the jury could so find, that defendant had no representation as to the drains, and that he had altered them in the exercise of his discretion under the contract. Mr. Turrell, for the respondent, urged that the verdict of the jury must stand, as there was ample evidence on which they could find as they had done. Mr. Justice Mathew, in giving judgment, said the sole question for the Court was whether there was evidence in the case on which the jury could reasonably find as they had done. He was satisfied that there was that evidence, and he was also satisfied that the learned judge, in his summing up, told the jury the law with great clearness. In fact, he represented the case in such a way that the jury, if they were disposed to take a favourable view of the defendant's conduct, had an opportunity of doing so, but they considered that the plaintiff had made out his case, and so found. The appeal would be dismissed with costs. Mr. Justice Wright concurred.

QUESTIONS AND ANSWERS.

[Readers are invited to ask through this department for any information which they may require on lines consistent with the objects of the paper. Every effort will be made to furnish satisfactory answers to all such inquiries. Readers are requested to supply information which would assist us in our replies. The names and addresses of correspondents must accompany their communications, but not necessarily for publication.]

C. H. W., Peterboro', writes: Can you inform me where I may obtain the best slate for blackboards? I have tested several kinds of composition offered as a substitute for slate for this purpose, but they are to my mind not satisfactory. I have examined the advertisement pages of the CANADIAN ARCHITECT AND BUILDER, without finding the name of any dealer in slate for this purpose.

ANS.—We understand that at Rockland, Que., slate is to be found which is well adapted for blackboards, and that a new company has recently purchased and undertaken to develop these quarries.

Charles E. Thibault and Joseph Perrault, have been registered to carry on business in Montreal as plumbers under the firm name of Thibault & Perrault.

FUNCTIONS OF THE BUILDER.*

THERE are apparently changes impending which may modify, if they do not transform, the office of the builder. On all sides we find people who are eager to introduce new arrangements. The system by which Great Britain is covered with buildings that are sound, commodious, and economical is, in the opinion of amateurs, out of joint, and wants mending. Hence it is we find good-natured people are eager to benefit the world by substituting for our experience the undisciplined boldness of outsiders.

This spirit reveals itself not only in the dreams of imaginative gentlemen who would desire to see the architect leading a body of craftsmen, while in some way he shares in their toil. It is seen, too, in the desire to have architects whose diplomas are evidence that they have mastered all the mysteries of construction, and are able to take our places. It inspires also the proposals of public bodies to dispense with builders. It gives point to the articles which the journals print whenever an accident occurs. The support which is given to strikes depends on the belief that we are in some way in the wrong. It is a curious fact, as exemplifying this tendency of the present that the member who was charged with the introduction of the last Registration Bill in Parliament imagined it was intended to apply to builders as well as to architects.

It is not in England alone that there is a wish to disturb arrangements which exist, because they are found to be in correspondence with the needs of the public. I have been told that a few weeks ago in Paris the Chief Administrator of the Department of Public Works declared in public that it was wrong to have a division between architects, engineers, contractors, and workmen, and that all their duties could well be fulfilled by one individual. In England we often hear similar propositions about rolling four single gentlemen into one, but in France the State out of the taxes creates both architects and engineers. Such amalgamation as was suggested on that occasion is equivalent to saying that the Government have been acting wrongly, and that public funds are misapplied. Yet such is the courage of the advocates of change, they will incur any sort of risk if it helps to advance their hobby.

I am not concerned with a defence of the French system of executing works. But I would ask, what evidence is there that English builders are not performing their work most satisfactorily? In spite of the extraordinary variations of our climate, how many buildings are cast down? Even among the defects of jerry-building want of stability is not included. Indeed, some artists lament the enduring powers of that class of structure. I am not disposed to maintain that builders are not fallible like the rest of humanity, but I do say that there is no business in the country which, taken as a whole, is conducted more honestly than our own. Nor should it be forgot en that in many cases the temptations to the contrary are very strong.

The proposals to erect dwellings and buildings in London by the County Council without the intervention of a contractor may be taken as an illustration of the lengths to which reformers or rather theorists are prepared to go. In an experiment of that kind everything works smoothly, for there is no risk. The defects in foundations or other natural obstacles need excite no alarm, for the cost of dealing with them is provided for. It will not be necessary to be alarmed about extra works or grieve over the deduction of items which were expected to be profitable. There is no anxiety about the chance of loss or any other contingency of the kind. The men employed will always be in good humour, and those who supply materials will always be in the most accommodating mood. Building in fairyland could hardly be more of a pastime than it will be under the County Council in London. But can you imagine, gentlemen, that so happy-go-lucky a method can be economical? We who have to suffer mental distress every day on account of the responsibility which we have assumed and who occasionally have to bring all our courage to bear in order to face our risks, know two well what the consequence will be. No doubt a very pleasant sight will be afforded when we find all who co-operate in a building working harmoniously together, but like all spectacles which are novel it will be found that money must be liberally expended on the arrangements. It will be said by the advocates of similar schemes that on private works in many places the builder has been already superseded. Drapers, co-operate stores, and providers of miscellaneous things are credited with having carried out important works very successfully at a fraction of the legtiimate charges. All those cases have never been properly scrutinized. If, for example, a co-operative store is able to furnish gasfittings at one-fifth the price which experts had estimated, is it not plain that the profit and loss account of the gaslighting department of the store was never properly made out? In all such cases a great number of departments have to be taken together and the loss in one of them is compensated by the gain in another. Then, again, when we hear that a draper has offered to do certain work in stone or iron far below cost price, we may always expect to find that he is to be allowed to supply goods that are within his province. For what he loses in construction he is able to refund himself by what he gains in furnishing. It would be easy to explain many other inconsisteneies, but I need not waste your time about them. The public may rest assured that in building works, no matter what agency they may employ, they will not gain more than if they had trusted themselves to a respectable and established builder.

We have no opportunities of performing such tricks of legerdemain. If by an oversight we under estimate the cost of work we have to bear the penalty. We have no means of finding compensation. We have no prospect of receiving payment for work which was not executed. In fact, I consider that if the advocates of revolutionary changes were aware of the liabilities of builders to incur loss, they would be somewhat less bold in bringing forward their schemes.

They are to be excused, however, for workmen who sometimes have been closely connected with us for many years appear to have a notion that all contracts are profitable. In no other way can I explain the tendency to strikes which has prevailed of late. Any cause seems to be sufficient to stop works. I will give the English workman the credit of being very honest. If he had not assured himself that there was more than sufficient profit in every case to meet his demand, he would hesitate before he created so much confusion. Of late years his demands have taken two forms—an increase of wages and a reduction of working. To discuss on what principles wages should be determined would take me too far on the present occasion. It is a vast subject, and one which has many sides. But I think I may say that the workmen of any district (Cardiff among others) would find in our association as reasonable advisers in their difficulties as they could select. The Council of the Association are bound to take a road view of the organization of which workmen form an important part, and they are not likely to under-value anything which would cause business to be stopped for a day if in an honorable way they could devise a remedy. I am sure that I am only expressing your minds when I say we have the fullest sympathy with our workmen. This is seen by the endeavours which are made to keep them with us. We are all proud of having workmen who have continued with us since their apprenticeship, and I have no hesitation in saying, incredulous as it may appear to skeptics, that one of the causes which lead so many of us into unprofitable contracts is the desire to retain an unbroken staff around us.

As regards working hours the question must be judged from another point of view. No doubt, gentlemen, your experience has been the same as my own, which is that in no department of life, outside the Government service, a man has not been able to advance himself who has been satisfied with working eight hours a day. All professional men must undergo greater toil unless they wish to remain at a low level. I am afraid our own business would hardly be profitable any day if we were satisfied with giving only eight hours attention to it. I see no reason, in spite of all my regard for the working classes, why they should have a much easier life than our own. As a rule, they have not only to work fewer hours, but they are free from responsibilities and other harassing sorts of wear and tear, which we must endure.

Some of you remember in your youth to have seen statements or tables which were prepared by Peter Nicholson, who once upon a time was accepted as an authority. He called them "Constants of Labour," and they were intended to show how much time was to be occupied with the most insignificant details of builders' work. I have never used Nicholson's "Constants," nor met a builder who employed them in preparing a tender. But I have no hesitation in saying that the time he assumed as a basis for his calculations would not correspond with what is now required. For all kinds of handwork more hours are indispensable than formerly. If the "Constants" were now in use they would have to be altered every year.

Now, this is a subject which does not concern us alone. The builder is in reality no more than an agent for the public, and whatever affects him must operate also on those who employ him. Strange to say, this undoubted fact is not realized. The public would seem to be indifferent when there are contests between workmen and builders. They appear to consider that the disagreeable affair is entirely circumscribed to the parties who encounter one another. For instance, is there a member among all those I have the privilege of addressing who can recall one case where he was told that he might proceed with deliberation in the erection of a building? The rule, as we all know, is to insist on the utmost expedition. We are bound under penalties not to go beyond a determined day.

Now, if buildings have to be erected as hitherto—i. e., without loss of time—is it not plain that with shorter hours and a diminution of the quantity of work produced in each of those hours, it will be necessary to employ far more hands, for which building owners will have to pay? By all means let the public become philanthropists. We are quite willing to keep works open for only a few hours every day, and to employ such a number of men that labour will need no exertion. But in that case they must not grumble at the amount of our tenders, nor go about bewailing the degeneration of builders.

There are, perhaps, very few of the public who are not more or less responsible for the condition of affairs which is supposed to make a reform of the building trade a necessity. They may not argue like the French official, the representative of the Minister of Public Works, to whom I referred at the beginning. He would lead the public to imag ne that it is possible for a workman, under a proper system of administration, to change places with an architect, engineer, or contractor. But by tolerating experiments like those of the London County Council, by encouraging dealers in cotton and soft goods, pins and needles, to go in for masonry, ironwork and sanitation, and by their unconcern during strikes and trade disputes they are helping to make workmen discontented. For my part, I believe that the worst sort of grievances to endure are those which are vague, and I am sure building workmen at the present time would suffer less if they defined what they want, and endeavored to discover how it could be realized.

As regards our trade, I suppose there never was a time when there were better facilities and more competence for executing work than there are at present. I am an advocate of the promotion of technical education, but I must say that I still believe the best school for young builders is to be found in builders' workshops. No branch among all the industries of England has been put to severer tests than ours. Styles of architecture change, and whatever is in fashion we are able to realize it with all the spirit of our predecessors. Greek, Gothic, Roman or Dutch buildings are alike to us. New requirements demand novel arrangements of construction, which are carried out as if they were an every day affair with us. In that way the history of any great building works become a sort of key to the industrialism as well as the taste of the age.

The public may not be able to appreciate all that we do at a right value. They cannot tell how much it costs to organize a system which will answer promptly and accurately every sort of demand that can be made upon it. But it is evident that at least one school of architects is able to realize how an ordinary builders' workshop can become an auxiliary to the architects office or the school of art. Some of you, gentlemen, may have seen the remarkable collection of essays entitled "Architecture: A Profession or an Art?" In the pages we find many things which reveal an altered recognition of the builder's importance. Thus it is stated "The contractor, the purveyor of labour, is not so far removed from actual building work as we architects, for he has, at all events, to know the nature and quality of materials, and he has generally passed through the workshop and learnt one or more trades, and made himself a handicraftsman. It would be an excellent thing if everyone who aspired to be an architect did the same, and learnt to do work with his hands as well as with his head." The example of the late Sir Gilbert Scott (a name that can never be mentioned by a builder, and especially myself, without reverence) might be cited as suggesting the value of some experience in a builder's workshop. When he had completed his articles in a London architect's office, he went direct to the offices of Messrs. Peto & Grisswell, to whom he gave his services in return for having the run of their workshop and their London works. There he acquired that knowledge which was of such advantage to him during a career which was marked by masterpieces.

* From the inaugural address at the meeting of the National Association of Master Builders of Great Britain, by Mr. Robert Dennett, President.

Dredging under ice with a steam shovel was a contractor's trick in excavating for some stone piers at Winnipeg, Man. The Red river at this point is 468 feet wide. The work was begun in February, according to the *Railway Age*, the shovel used being a very powerful machine manufactured by the Vulcan Iron Works Company, of Toledo, O. The work was done by W. G. Reid, a Montreal contractor of large experience in bridge work. An ordinary track was first laid to within about 30 feet of a hole (22 x 60 feet) cut in the ice, which was about 2½ feet thick, over the proposed location of the first pier, from which point heavier ties, 8"x8"x10', laid 2 feet apart, were used. At the immediate edge of the hole were placed three long ties 10 inches in diameter and 50 feet long, and over this track the shovel was worked to within 6 inches of the edge of the hole, where it was securely anchored with blocks and chains. After a distance of about 10 feet in length along the full width of the hole had been excavated, a bent 888 feet and 13 feet 6 inches in height made of 10-inch timbers was sunk to the level of the ice, and cross-timbers 50 feet in length laid down, thus distributing the weight equally upon the ice and the bent. This method was continued until the whole excavation necessary for each pier was completed. The material excavated was discharged from the bucket upon sleds and hauled away.

CORRESPONDENCE.

[Letters are invited for this department on subjects related to the building interests. To secure insertion, all communications must be accompanied by the name and address of the author, not necessarily for publication. The publisher will not assume responsibility for the opinions of correspondents.]

THE PLUMBER'S PROFITS.

Editor CANADIAN ARCHITECT AND BUILDER.

SIR,—While coinciding with the remarks appearing in your June issue anent the necessity of the plumber satisfying himself that his client is not made to pay for time which has been loitered away by journeymen and apprentices, I wish to call attention to the fact that the plumber's profits are by no means what they are frequently pictured to be. Competition is not less keen in the plumbing business than in other branches of the building trades, nor have the effects of this competition been less in the direction of reducing profits. There is this difference, however, as compared with some of the other trades, that plumbing material is of a very expensive character, and the plumbing work is expensive in consequence. A glance over the list of plumbers in Toronto to-day fails to show more than one or two who have succeeded in accumulating even a competency out of the profits of their business. This fact should in itself suffice to refute the charge that the plumber asks or receives exorbitant prices for his work. I hesitate not to say that there is probably no class of business men in the community who get smaller returns from their business than do the plumbers.

Yours truly,

JUSTICE.

ONTARIO ASSOCIATION OF ARCHITECTS.

THE supplemental examinations for 1893 will be held on September 27th and 28th.

* * *

The Association library has received from the Architectural Club a gift of Lübkes History of Art. The Architectural Club, in winding up its affairs, found a surplus on hand, which it expended in this way.

DECORATION AND FURNITURE

A CRITICISM.

THE *British Architect* prints the following criticism of the illustration of a carved stone mantel which appeared in a recent number of this journal: In the CANADIAN ARCHITECT for May there appears an illustration of a carved stone mantel for a private residence in Toronto, which shows a grotesque face looking out from the centre of a mass of foliage ornament. The face, which has strongly marked features, is on the broad grin, of that type associated with the goblins of the nightmares of one's childhood. The head is covered with a flowing mass of rough tangled locks, and round the neck is a sort of collar, from each side of which stretch out the goblin's wings. We cannot say we appreciate this kind of thing inside the home, though it may be all very well in gurgoyles outside the building. As it is shown in this mantelpiece it is, however, decidedly out of place as an ornamental feature, and we can well imagine the time when to a sensitive child such an apparition would call up all sorts of horrible imaginings. But perhaps the lady for whom it has been executed, married though she be, has no children, or, if she has, expects them to be quite as strong-minded as herself in respect to grinning grotesques and hobgoblins.

CONTRAST OF COLORS IN NATURE.

NATURE is very sparing of showy contrasts of warm and cold colours, says Mr. W. Barnes in a recent issue of the *Architect*. Red and blue are very rare, and of yellow and blue the cases are but few, and black and blue are found in lepidoptera more often than white and blue are seen in our flora or fauna. It is not uncommon for one of two strong colors to be overcast with a tinge of its fellow, or for both of them to be reconciled by a common touch of black or of some third colour, or for one of them to be lightened by a dash of white, while the other is lowered by as much black; and so red off-hued with black—russet and green upbrightened with white—often meet in the autumn in dead and dying patches of fading leaves. It may be shown, I believe, by the refractions of light in crystallised gypsum that brown is the complementary colour to lavender-grey; and how true to herself is Nature, we may go forth and see in the fall of the year; in the dead and curled leaves of the mugwort, or meadow sweet; which are beautiful even in their death, with one side brown and the other the brown-matching grey; and if brambles be cut in the leaf-greeny season, their two surfaces soon wither into the harmony of grey and brown. And what use are we to make of these hues of nature? They are warrants for a grey mantle under locks of brown hair, or a brown bonnet or trimmings, or a grey room wall with brown furniture; and if on a hot summer's day, I see the dark leaf shades playing on the grey bark of a young beech, I can boldly lay darkish leaf shades on a wall of the beech bark's hue; or if, after the winter rains, I find a barkless pole in railings, tinted with the palest blue-grey, and on breaking off a splinter of it I find its inner wood of its true colour of pale brown yellow, why should I not take the inner tint for my wall and the outer one for the skirting? Or, if I pick up a piece of lichen of dull green on one side and dull grey on the other, why should I not bind my book in one colour and lay on it a lettering piece of the other? Nature is the best school of art, and of schools of art among men, those are the best that are Nature's best interpreters.

THE CANADIAN CONTRACTOR'S HAND-BOOK.

THE second edition of this book which has recently left the press, has already had quite an extensive sale. We append a few opinions of the book as expressed by some of the leading papers:—

The *Monetary Times*: This is a compendium of useful information for persons engaged in works of construction, containing upwards of 150 pages. That it has been found of service is proved by the fact that the present is the second edition. First, and appropriately, appears the text of the Mechanics' Lien Act of 1877, and that of 1890 for simplifying procedure; also the consolidated Act respecting workmen's compensation, and Toronto and Montreal building by-laws. Next a glossary of terms used in building, notes on estimating—which seem to us very practical and valuable—and various tables having relation to the strength of materials and the weight of substances. A feature which to employers is worth the whole price of the book is the table giving the amount of a workman's wages for any number of hours, from 2 to 120, at rates per hour ranging from 15 cents to 45 cents. Then there are "Hints" for painters and paperhangers, "Points" for plumbers, &c., &c. Send to Charles H. Mortimer, publisher, Confederation Life Building, Toronto, for a copy, price $1.50; to subscribers of the CANADIAN ARCHITECT AND BUILDER, $1.

The Toronto *Mail*: "The Canadian Contractor's Hand-Book," by Chas. H. Mortimer (Toronto: Canadian Architect and Builder Press). This little book, which is a compendium of useful information for persons engaged on works of construction, is not to be estimated by its size, its value being greater than the number of cubic inches it occupies. In the pocket of the builder, the bricksetter, the stonemason, the joiner, and many other persons it will be found frequently useful. Besides a copy of the Mechanics' Lien Act, the Compensation to Workmen Act, and various by-laws relating to the building trade, it contains numerous useful tables and receipes, all of which have been carefully selected, and are applicable to daily use.

PUBLICATIONS.

We have been favored by the secretary with a copy of the calendar of the Architectural Association, of London. It comprises 200 pages of useful data relating to the Association, including the constitution and by-laws, form of application for membership, syllabus of meetings, curriculum, reports, list of members, etc.

We extend our congratulations to our esteemed Antipodean contemporary, the *Australasian Builder and Contractors' News*, which has lately celebrated its sixth anniversary. It is one of the most interesting of the many architectural journals which come regularly to our table, and is deserving of the largest measure of encouragement and support from those in behalf of whose interests it speaks.

We are informed that the Toronto Radiator Mfg. Co. have now in the printer's hands a catalogue which gives promise of being the most elaborate and expensive production in this line that has been executed in Toronto for a number of years. The volume is to contain some 200 steel plate views of Canada's best buildings, in addition to the usual illustrations of the Safford patent radiators and a carefully prepared treatise on Hot Water and Steam Heating.

The July *Cosmopolitan* will mark the most radical step ever taken in periodical literature. With that issue the magazine, unchanged in form, in fact, one of the best numbers of the *Cosmopolitan* ever issued, will be put on sale at *twelve and one-half cents per copy—$1.50 a year*. The cutting in half of a price already deemed low for an illustrated magazine is the result of an intention long since formed, to give to the public an illustrated monthly of the very highest class at such a price as must bring it within the reach of all persons of intellectual tastes, however limited their income.

PERSONAL.

Peter Belanger, contractor, Ottawa, is dead.

B. Mooney & Sons, builders, St. John, N. B., have dissolved.

The death is announced of Mr. Edward McCoskrie, architect, Victoria, B. C.

Mr. W. H. Carrick, manager of the Gurney Foundry Co., Toronto, is visiting the World's Fair.

We regret to learn of the accidental death of Mr. N. D. McDonald, a well known plumber of Winnipeg. While getting off an electric street car he was struck by a passing bicycle, receiving injuries which shortly after caused his death. Among some of the important contracts carried out by Mr. McDonald was the plumbing in the Hotel Leland, the Manitoba College, the Grain Exchange and the Barracks.

RUSKIN ON BRICKMAKING.

OUR fields of good clay were never given to us to be made into oblong morsels of one size. They were given us that we might play with them, that men who could not handle a chisel might knead out some expression of human thought. In the architecture of the clay districts of Italy, every possible adaptation of the material is found exemplified, from the coarsest and most brittle brick used in the mass of structure, to brick for arches and plinths cast in the most perfect curves, and of almost every size, strength, and hardness; and moulded brick wrought into flower work, and tracery as fine as raised patterns upon china. And just as many of the finest works of the Italian sculptors were executed in porcelain, many of the best thoughts of their architects were expressed in brick, or in the softer material of terra cotta; and if this were so in Italy, where there is not one city from whose towers we may not descry the blue outlines of the Alps or Appenines, everlasting quarries of granite and marble, how much more ought it to be so among the fields of England?

Jean Marie and Louis T. Aubin have been registered partners to carry on business as builders at Montreal under the style of Aubin & Frere.

SANITATION AND HEATING

ASSOCIATION OF EXECUTIVE HEALTH OFFICERS.

THE eighth annual meeting of the above Association was held at the city of Guelph, Ont., on the 27th and 28th of June. The proceedings were presided over by the President, Mr. Willis Chipman, C. E.

An address of welcome was presented by the mayor, and by the Local Board of Health.

Four sessions were held, one of which took the form of a public meeting, to which the citizens were invited.

Among the papers presented and discussed were the following :—"Diphtheria Epidemics and how Principally Propagated," by C. A. Hodgetts, M. D., Toronto ; "Notes on the Prevention of Disease," by A. Groves, M. D., Fergus ; "Toronto Water Supply," by J. J. Cassidy, M. D., Chairman Provincial Board of Health, Toronto ; "Defences of the Province against Cholera," by J. Coventry, M. D., Medical Health Officer, Windsor ; "Our Schools in Relation to Health," by Prof. J. Mills, M. A., President Agricultural College, Guelph ; "The Danger of a Smallpox Epidemic," by P. H. Bryce, M. A., M. D., Secretary Provincial Board of Health, Toronto ; "Systems of Sewerage available for Ontario Towns and Villages," by Alan Macdougall, C. E., Toronto ; "Public Abattoirs, their Necessity and Benefits," by J. Wallace, M. D., Alma.

The following are the officers elect for the ensuing year :—President, Dr. Cameron, Owen Sound ; First Vice-president, Alan Macdougall, C. E., Toronto ; Second Vice-president, Dr. Howitt, Guelph ; Secretary-treasurer, Dr. P. H. Bryce, Toronto ; Executive Committee, Dr. Hall, Chatham ; Dr. Coventry, Windsor ; Dr. Sheard, Toronto ; Dr. Griffin, Brantford ; Dr. McCrimmon, Palermo.

NEW PLUMBING BY-LAW OF THE CITY OF MONTREAL.

FOLLOWING is the text of an ordinance which is about to be adopted in the city of Montreal for the regulation of plumbing. This ordinance has been revised by and received the approval of the Montreal Sanitary Association. We are assured that the ordinance will probably pass the Council without material amendment :

Sec. 1. All plumbing and house drainage in the city shall be made and constructed in accordance with the following rules, which shall be binding on all parties concerned :

(1)—No drain or plumbing work shall hereafter be made unless plans, drawings and a description of the same shall have been previously deposited by the proprietor, or his representative, in the health office, at least eight days before the commencement of the work, and unless such plans and drawings shall have been approved of by the authorized officer ; and in case of repairs or alterations affected by sanitary regulations, notice shall be given to the health department within 24 hours ;

(2)—No part of the work shall be covered or concealed in any way until after it has been examined and approved of by the inspector ; and notice shall be given to the health department when the work is sufficiently advanced for such inspection ;

(3)—The water department shall refuse to turn on the water unless the demand for the same is accompanied by a certificate of the inspector, to the effect that the work has been inspected, and found to be in accordance with said rules ;

(4)—The material used shall be of good quality and free from defects, and the work shall be executed in a thorough and workmanlike manner ;

(5)—The arrangement of the soil, waste and ventilation pipes shall be as direct as possible ;

(6)—The soil, drain, waste and ventilation pipes shall, if practicable, be at all times exposed to view ready for inspection and for convenience in repairing ;

(7)—When necessarily placed within partitions or recesses of walls, soil, drain, waste or ventilation pipes shall be covered with woodwork so fastened with hinges, or round headed screws, as to be readily uncovered ;

(8)—Every house or building shall be separately and independently connected with the street sewer, in front of such house or building, or with such other sewer as shall be designated by the board of health ;

(9)—Every house drain shall be of iron, with a fall of at least ¼ inch to the foot, and no joint shall be made directly under the wall of the house ; moreover, where water-closets discharge into it, it shall be at least 4 and not more than 6 inches in diameter, and be laid in a straight line if possible. All changes in direction shall be laid with curved pipes and all connections with Y branch pipes and curved bends ;

(10)—Every such drain put in and covered without due notice to the health department shall be uncovered for inspection within 24 hours, if required by the inspector ;

(11)—No brick, sheet metal, earthenware or chimney flue shall be used as a sewer ventilator, or to ventilate any trap, drain, soil or waste pipe ;

(12)—Soil pipes shall be of cast iron of the weight specified in subsection 20, and shall extend at least two feet above the highest part of the roof or coping, light, shaft louvres, window or other opening ; they shall be of the same size throughout, and in no case shall they be less than four inches in diameter ; no cap or cowl shall be affixed to the same ;

(13)—Soil, waste and vent pipes in an extension, shall be carried above the roof of the main building when they are closer than twenty feet to the windows of the main building or adjoining houses ;

(14)—The vent-pipe from the horn of a water-closet shall be required only when the closet is at a distance of fifteen feet from the main ventilation pipe of the drain ;

(15)—Rain-water leaders shall not be connected with sewers unless by special permission of the board of health ;

(16)—Joints of sewers and soil pipes shall be gas and water tight ;

(17)—When no water-closet exists, ventilated in accordance with the rules aforesaid, the main waste pipes shall be of lead or iron of the weight specified in subsection 20, and shall be not less than 2 inches in diameter unless there are more than four sinks, in which case the size shall be 3 inches in diameter ; and every such pipe shall be continued full size through the roof in the manner prescribed for soil pipes ;

(18)—When lead pipes are used to connect fixtures with vertical soil or waste pipes, or to connect traps with vertical vent pipes, they shall not be lighter than six lbs. sheet lead to the foot ;

(19)—There shall be no traps in connection with vertical soil or waste pipes, unless by special permission of the board of health ;

(20)—All pipes shall be sound and free from holes or cracks ;

(21)—The following weight per lineal foot shall be accepted as standard :

IRON PIPES.

For plumbing work.

2 inch 4 pounds per lineal foot.
3 " 5 " " " "
4 " 9 " " " "
5 " 12 " " " "
9 " 15 " " " "

For drain work.

4 inch 12½ pounds per lineal foot.
5 " 16 " " " "
6 " 20 " " " "

LEAD PIPES.

For waste sink pipes.

2 inch 10 pounds per lineal yard.
4 " 15 " " " "

Lead waste pipes, bends or cesspools shall be equal to not less than 6 lbs. per square foot of sheet lead ;

(22)—The fittings used in connection with such pipes shall correspond with them in weight and quality ;

(23)—No tar-coated cast iron pipes shall be used ;

(24)—The plumbing work shall be tested by the Inspector in the presence of the plumber, (when the latter is required to be present) with the peppermint, smoke, water or any other test approved by the board of health ;

(25)—When defective pipes are discovered, they shall be removed and replaced by sound pipes ; defective joints shall be made tight and every part of the work in which defects are found shall be made to conform to the present rules ;

(26)—Joints in iron drain, soil and waste pipes, shall be so filled with oakum and lead and hand caulked so as to make them gas tight, and they shall not be painted, varnished, tarred or puttied over until after inspection, unless the inspector does not signify his approval or disapproval of the work within 36 hours after the health department shall have been notified that the work is ready for inspection ; the said joints may also be screwed joints ; should the work prove to be satisfactorily executed in the judgment of the inspector, he shall grant a certificate to that effect to the person concerned ;

(27)—All connections of lead with iron pipes shall be made with a brass or copper sleeve or ferrule of the same size as lead pipe, put in the hub of the branch of the iron pipe and caulked with lead ; and the lead pipe shall be attached to the ferrule by a wiped or overcast joint ;

(28)—All connections of lead pipes, shall, where practicable, be by wiped joints ;

(29)—No tile pipe shall be connected with the soil or waste pipe unless the same be provided with a flange to admit of a proper connection being made ;

(30)—Every water-closet, urinal, sink, basin, wash tray, bath, and every tub shall be separately and effectively trapped. This rule shall apply to a set of tubs, but only one trap shall be required for the set ;

(31)—The connections between iron and tile pipes shall be made with the best Portland or Roman cement, or by such other mode as may be approved of by the board ;

(32)—Traps shall be placed as near the fixtures as practicable, and in no case shall they be distant more than two feet from the fixtures ;

(33)—There shall be only one trap under the water-closet and that immediately beneath the same ;

(34)—All waste pipe fixtures other than water-closets, shall be provided at the inlet of such fixtures with strong metallic strainers to exclude from such waste pipes all substances likely to obstruct them ;

(35)—In no case shall the waste pipe from a bath, tub or other fixture be connected with a water-closet trap ;

(36)—Overflow pipes from fixtures shall in every case be connected within the inlet side of the trap, and above the water ;

(37)—Drip or overflow pipes from the safety pan under water-closets and other fixtures, or from tanks other than those of water-closets or refrigerators, shall be made to run into some place in open sight ; and in no case shall any pipe be connected directly with the drain, waste or soil pipe ;

(38)—Water-closets apartments shall open to the outer air, or be ventilated by means of a window, shaft or air duct, or by a vent shaft to the chimney ;

(39)—Interior water-closets shall in no case be supplied directly from the city reservoir supply pipes ;

(40)—In tenement houses containing more than one family, there shall be one water-closet for each family and a separate cistern for each closet ; in other houses, however, a group of closets may be supplied from one tank ; but not water-closets on different floors ;

(41)—The overflow pipes from water-closet cisterns shall discharge into an open sink, or the basin of the water-closet, or where its discharge will attract attention and indicate whether waste of water is occurring into the soil or waste pipe or into the drain ;

(42)—Valves must be so fitted and adjusted as to prevent wasting of water ;

(43)—No privy vault or cesspool for sewerage shall be permitted in any part of the city where water closets can be connected with a public sewer in the street ; when no sewer exists in the street a permit for a temporary privy may be granted by the board of health ; and in such case it shall be water tight, of a capacity of 45 cubic feet ; the sides and bottom shall be constructed of cemented brick twelve inches in thickness and well cemented inside ; such vault may be constructed of cast iron, the shape or form of which shall be either circular or oblong without angles, and with a concave bottom ; it shall be provided with a ventilation pipe at least 4 inches in diameter, extending from the pit through the roof, sufficiently high as to prevent inconvenience to occupants of neighboring houses ; the seats shall have a tight fitting cover ; it shall have an aperture opening exteriorly to allow of cleaning by pneumatic process, such aperture to be 2 feet by 1½ feet in size ; or else the flooring shall be air tight and shall have a tightly fitting trap door communicating with the pit ; the top of the vault shall be one foot above the level of the ground ; nothing shall be put into such pit, excepting human excreta ; privies shall be located at a distance of 20 feet (or more according as the board of health may deem necessary) from any house or street ; they shall be emptied when the contents reach to within eighteen inches of the top of the vault, or when judged necessary by the board of health, by persons appointed by the board ; no offensive smell or gases shall be allowed to escape therefrom. But, in no case shall a privy be allowed within the walls of a dwelling house ;

(44)—No steam exhaust, blow off pipe shall connect with a sewer or any house drain, soil pipe or waste pipe ; such pipe must discharge into a tank or condenser ;

(45)—Cellars shall not be connected with the house drain unless necessary, and by special permission of the board of health, and according to plans approved of by the board ;

(46)—A sub soil drain shall be provided when necessary, and shall be constructed and trapped to the satisfaction of the board of health ;

(47)—No trap shall be permitted between the house drain and the public sewer, unless by permission of the board of health ; conditionally however that such trap shall have a handle-hole for cleaning purposes and a fresh-air inlet pipe the whole as may be decided upon by the board of health ;

(48)—Drains in yards shall, in all cases, be trapped below frost, that is to say : four feet at least under ground ;

(49)—In the case of privy vaults now drained into a common sewer, they shall be isolated by means of suitable traps placed below frost and according to instructions from the board of health ;

(50)—In the case of a new house being built or one already existing being prepared, wherever there is a public sewer in the street, a water-closet shall be put in, to the exclusion of privy pits ;

(51)—The inspection of drains as well as the inspector of drains shall be under the exclusive control of the board of health ;

Sec. 2. The word "board," wherever it occurs in this by-law means the board of health of the city of Montreal ; and the word "inspector" means the inspector appointed by the said board to carry out the provisions of this by-law ;

Sec. 3. Any person contravening any of the provisions of the present by-law shall be liable to a fine, and in default of immediate payment of the said fine, and costs, to an imprisonment, the amount of said fine and the term of said imprisonment to be determined by the Recorder's Court, at its discretion ; but the said fine shall not exceed forty dollars, and the term of imprisonment shall not exceed two calender months ; the said imprisonment however to cease at any time before the expiration of the period fixed upon by the Recorder's Court, on payment of said fine and costs and where the infraction is continuous, such infraction during each day, shall constitute a saperate offence.

COMBINATION HEATING.*

THE word "combination" may be defined as the result of combining or joining together two or more different elements or systems into one harmonious whole. There are several distinct and different systems of heating, and the combining of any two of these systems into one would naturally result in a combination system. The specific form of combination heating which I wish to treat of is obtained by a combination of steam or hot water and air, or, as it is commonly called, furnace heat. The advantage of the combination system in buildings suitable to its use are manifold, but in order that these advantages may be made apparent, it may be necessary to diverge a little. Heat is supposed by many to be an actual and discernible substance, and until within a very few years even the more advanced students of natural physics were of the same opinion. Later investigation has shown that heat is nothing more or less than molecular motion, consisting in case of air of nearly uniform rectilinear motions, with sudden changes in direction and velocity when the molecules come too near one another ; in case of a liquid of irregular wandering of its molecules, and in case of a solid or orbital or oscillatory motions. By the foregoing definitions it will be readily seen that air will absorb heat much more rapidly than either liquids or solids, and as in combination heating we are depending for fully fifty per cent. of our heat on air heat, the natural conclusion is that a combination heater will give results in the rooms to be heated much quicker than either straight steam or straight hot water.

Heat is communicated from one body to another in three ways, viz. : Radiation, convection and conduction. Radiant heat passes from one body to another at a distance through the air in straight lines and with great velocity, but it does not, to any appreciable extent, warm the air through which it passes. Conducted heat passes from one particle of matter to another at insensible distances, as an iron bar with one end in the fire becomes gradually heated at the other end. Convected heat is the movement of the heated body itself from one point to another, as the circulation of hot air or hot water. In combination heating we again have an advantage over straight steam or hot water, as we utilize in the rooms to be heated two or three processes of heat distribution—*i. e.*, radiant and convected heat—while in steam or hot water only the radiant heat is utilized.

One of the most important features of combination heating is the fact that where the air supply is taken from the outside, as it always should be, it ensures a perfect ventilation throughout the building, as well as heat. The necessity for ventilation is very little appreciated by the general public, but as heating and ventilation have always seemed to me to be inseparable, and as the people naturally turn to our profession for their knowledge of these matters, it might be well for me to ask, What is ventilation, and why is it necessary? Ventilation is the act of replacing foul, impure air, in a confined space, with pure air. Please note that word "replacing." Times without number have I had people assure me that they had looked out for the ventilation of their house, as they had fireplaces in all the principal rooms. When asked if they did not know that "Nature abhorred a vacuum," and that their fireplaces would not exhaust unless there was some means provided for replacing the air thus removed, would reply, "They had not thought about that, but guessed there would be enough leaks in the doors and windows anyway." I could cite any number of leading authorities and read whole chapters showing the necessities of ventilation and the vast consequences of the result of continued breathing of impure air, but a mere statement of the component elements of air will suffice for this article. If we divide air into 10,000 parts, its composition would be as follows : Oxygen 2,096, nitrogen 7,900 and carbonic acid 4 parts. When the proportion of carbonic acid in a room is increased from the normal amount of 4 parts in 10,000 to between 5 and 7 in 10,000, a faint, unpleasant odor is usually perceptible to one entering from the fresh air ; if the proportion reaches 8 per cent the room is said to be close. According to some authorities, a full-grown man at rest will exhale through the pores of the skin and from his lungs nearly ¾ cubic foot of carbonic acid per hour. Taking a room containing 2,500 cubic feet of air in its normal condition, we find that the air contains 1 cubic foot of carbonic acid. Now, let us suppose this room to be a sleeping room, not ventilated, occupied by two persons eight hours each night. If the windows and doors of the room were closed during the eight hours, the natural portion of carbonic acid would be increased to about 13 cubic feet (or 1 part to 200), and the occupants would arise in the morning with depressing headache. A person coming into the room from the outside would declare the air to be "foul," and a man does not need to be a crank on ventilation to reach the conclusion that such a situation would be anything but healthful. This condition could be obviated, to a certain extent, by raising the windows, but that practice is dangerous in results, is a prolific source of colds and sickness, and as a means of ventilation totally unreliable, not to mention the morning's discomfort of arising in a cold room. Accurate ventilation will replace the air in a given room every 20 or 30 minutes without draft.

I wish to call attention here to the reason why the combination heater will from natural causes give more perfect and greater results in ventilation than it is possible to obtain from indirect

* Abstract of paper read by Mr. Geo. Hoffman before the National Association of Steam and Hot Water Fitters.

steam or hot water, more particularly hot water. The force which we use to crowd the fresh air into the room and drive the foul air out is due to the expansion of the fresh air by heat. Air expands one-four-hundred-and-ninety-first of its bulk for every degree it is heated above 32° F.

Thus it will be seen if we heat the air 55° warmer than the surrounding air we have increased its bulk very nearly one-tenth. The greater the difference in temperature the greater the expansion, and, as a natural consequence, the more rapid the movement of the warmer air. On a moderate winter day the indirect radiator in a hot water job is rarely heated over 130° to 140° F., and as it is not possible for the air in passing through the stack to absorb more than from one-half to two-thirds of the heat, the temperature of the air flowing into the room under such conditions will rarely exceed 75° to 80° F. As the force with which the air comes into the room depends upon the difference in temperature of the air in the stack and the air in the room, it will be readily seen that the movement must be very sluggish. With the combination heater, the air coming in contact with the fire and smoke surfaces only, the temperature is raised much higher, with the result of a rapid flow of a large volume of air into the room in question.

Now, one more point, then I am through. In installing a combination job great care should be taken to place the heater as near the centre of the work as possible, locating all air registers as near the heater as practicable, so as to insure short connecting pipes in the basement. Always locate registers away from windows or cold walls, selecting, if possible, the warmest side of the room. Cold and warm air are always antagonistic, and you should give the warm air all the advantage possible if you wish for the best results.

Lastly, the combination system of air and water heating particularly is in the market to stay, and to you who are interested in residence or school heating the subject is worthy of your most careful consideration.

USEFUL HINTS.

Fine bolted whiting is a good thing to add to graining color for oak when it is desired to thicken it without changing the shade. Melted beeswax, or soap dissolved in hot water, and added to the color while warm, may also be used.

According to a contemporary, sheet brass may be cut chemically with success by the following method: Make a strong solution of bichloride of mercury in alcohol; draw a line across the brass with a quill pen, where it is to be cut. Let it dry on, and with the same pen draw over this line with nitric acid. The brass can then be broken like glass cut with a diamond.

The art of producing mosaics is, according to an American contemporary, being extended to leather, the pieces being variously colored, some having metallic hues, others with a transparent glaze over another color. They are attached by glue to a hardwood ground, framed the depth of the pieces, which are shaped as required.

The formation of efflorescence takes place in the following manner: Bricks made from clay, having a high percentage of the sulphates of magnesia, soda or potash in their composition, and not sufficiently fired to fuse or amalgamate them with the silicates and oxides of iron, will readily dissolve the alkalis on becoming wet, and with the evaporation of the moisture a large quantity is carried to the surface and deposited in crystalline form.

FIREPROOF MORTAR.—Mortar for resisting the action of fire, and proper to be employed in building slight brick piers as substitutes for, or instead of employing, iron columns, may be made of pozzolano mixed with fresh-ground lime of chalk from the lower beds; and as real pozzolano is an imported substance and likely to be expensive, its place may be very well supplied by an artificial substance of similar character, produced by burning any marly clay that is fit for brickmaking to a gray clinker, and reducing such clinker to a grain of the size of gray sand. Three-fourths of this substance to one-fourth of fresh-ground lime, mixed dry in the first instance, and, when so mixed, rendered plastic by the addition of soft water, will yield a mortar capable of resisting fire for a long time, and water, if need be, as long as any bricks that can be set in it.

A plastered ceiling that is very loose and almost about to fall, may sometimes be saved by the following method: Form of two or three pieces of scantling, and ordinary laths, a frame long enough to cover the defective part. Hold this against the ceiling by means of two uprights and gently press back the loose plaster against the underside of the joists, supporting the lower portions of the uprights by means of wedges. Now take some ordinary wrought nails, and file slots into their heads so that they may be driven home by means of a screwdriver. Use a sharp screwdriver and press each nail gently through the plaster into the joist, giving each a twist when it has entered the wood. If this is done carefully, the plaster will not be disturbed, but will be held perfectly when the framework is taken away. A little plaster of Paris, for filling up the holes will give a very good job. For safety the ceiling is best papered before being whitened.

COAL-TAR FOR WATERPROOFING.—The use of coal-tar for waterproofing masonry is recommended by a French technical journal. For surfaces exposed to the air it is advised to apply from one to three coats boiling hot. Its durability is increased by adding a small proportion of India-rubber dissolved in benzine. If the color of the coating is objectionable, it may be dusted with plaster-of-Paris before drying. Where surfaces are to be covered with earth a single coating of tar made thick by blazing is preferable. A small quantity, two or three gallons, is brought to a boiling temperature and lit at the surface. It is allowed to blaze and kept constantly stirred at the same time until the volume is considerably reduced and it becomes pasty on cooling. The product is spread as rapidly as possible with a large flat brush, which is dipped often to prevent cooling. A single coat applied in this manner adheres firmly to even the smoothest surface.—*Invention.*

A recent invention, says the American *Upholsterer* intended to supersede the heavier wood ceilings, is a light and handsome wood veneer. This consists of a thin layer of natural wood on a background of paper, which is placed upon the ceiling in about the same way that ordinary wall-is laid—only to attain perfect results it is first necessary to coat the surface to be employed with a thin layer of muslin. This ceiling when completed is, if anything, more artistic in appearance than those of heavy inlaid wood. The cost of treating a ceiling in this way is much less, and the great variety of woods and their easy attachment seems to give a wider latitude for beautiful effects. There is hardly any combination of color that cannot be formed out of the natural wood. The white bird's-eye maple, curly maple, white holly and pink bird's-eye maple form a combination that is beautiful in its light and chaste effect. The union of the laurel burl, figured walnut and amaranth is most taking in appearance. The dark, rich colours of these woods blend into perfect harmony.

MANUFACTURES AND MATERIALS

Quite a demand for Canadian lumber is reported from St. Johns, Nfld., where large building operations are in progress.

The Consolidated Plate Glass Company of Canada, Limited, has been incorporated, with a capital stock of $250,000.

Mr. E. B. Jarvis, architect, Toronto, has invented and patented a system of heating and ventilating. The Toronto Radiator Mfg. Co. will manufacture the apparatus.

The Paterson Manufacturing Company, with chief place of business at Toronto, is being incorporated with a capital stock of $50,000, to manufacture building paper, roofing material, etc.

At one of St. George granite quarries the other day, says the *Sun*, a block was taken out 32 feet long, 18 feet wide and 15 feet thick. It is computed that this block of stone when loaded on a car will be worth $5,000. It contains about 250 tons of stone.

The Company which is being organized in Victoria, B. C., to manufacture Portland cement expect to find a profitable market in China and Japan. The cement manufactured in those countries will not it is said stand for any length of time under water, and half a million dollars worth of English cement is imported annually.

We understand that the Toronto Radiator Mfg. Co. are preparing a very large shipment for Tientsin, North China, and that they export very largely to Great Britain, France and Germany. They also ship to the United States. In certain parts their goods are preferred to those manufactured there, and the consumers are satisfied to pay the additional 45% duty and use the goods manufactured in Canada, which speaks well for Canadian industry.

Messrs. W. R. Melville, E. P. Brammer, W. H. Robertson and S. E. Manuel are the owners of 200 acres of land on Cortes and Rugged Islands, about 90 miles from Vancouver, B. C., which has been found to contain an unlimited supply of red granite of excellent quality. The quarry is situated on a good harbor, the depth of water making it possible for vessels of any tonnage to approach close to shore. The stone will shortly be placed on the market.

At a meeting of the Consolidated Plate Glass Co., of Canada, Limited, held at Toronto on the 4th inst., the following gentlemen were elected directors: Frank J. Phillips, William Ferguson, Edwin Hill, William G. Phillips and Joseph McCausland, of Toronto; William R. Hobbs and Thomas S. Hobbs, of London, Ont.; Alex. Ramsay and L. I. Boivin, of Montreal, and George Howe, of Ottawa. At a subsequent meeting of directors, Frank J. Phillips was elected president and William R. Hobbs and Alex. Ramsay, vice-presidents.

CREDIT VALLEY BROWN STONE

From Carroll & Vick's No. 6 Quarry, Credit Forks, Ont.

SANDSTONE, fine grained, reddish brown. Contains quartz, and a little felspar and mica. The stone is in beds of four feet and under, and can be handled in pieces up to five tons. Quarry 300 yards from Railway.

Specimen.	Section under Pressure	Height.	Crushing Load.	Crushing Stress per sq. in.	Average Crushing Stress per Square Inch
	Ins.	Ins.	Pds.	Pds.	Pds.
A	.....	.....	.....	.....	
B	2 3/8 × 3	2 7/8	131,000	15,188	
C	2 11/16 × 3	2 7/8	130,000	14,751	
D	3 × 3	2 7/8	133,000	14,777	14,905

14,905 pounds is the average crushing strength per square inch of our Credit Valley Brown Stone.

The highest standard of test attained by any pure Sandstone in America.

IN confirmation of the facts above stated, we have pleasure in directing your attention to the accompanying table, showing the result of the test of our stone, in connection with the series of tests of building stones conducted in 1892 at the School of Practical Science, Toronto, under the direction of a committee of the Ontario Association of Architects.

By referring to the results of the tests above mentioned, it will be seen that the average crushing stress of the majority of Canadian and American sandstones is far below that of ours, the difference in our favor ranging from 75 to 50 per cent.

The Credit Valley Brown Stone, owing to its modest tone, harmonizes beautifully with red or cream colored brick.

It has been reported that there is difficulty in obtaining Credit Valley Brown Stone. To correct this mistaken notion, we wish to state to architects and the public that we have 40,000 cubic feet of stone ready to ship on the shortest notice, which can be followed up with an unlimited supply. Last year we made extensive additions to our plant and opened up new quarries and mines, and will supply promptly all orders given to us or our agents.

MAPLE HILL - ONTARIO

STONE UNDER THE MICROSCOPE.

It is often held that the best method of determining the probable durability of a building stone is to study its surface, or thin transparent slices, under a microscope. This method of study in recent years has been most fruitful in developing interesting and valuable knowledge of a scientific and truly practical character. An examination of a section by means of the microscope will show not merely the various substances which compose it, but also the method according to which they are arranged, and by which they are attached to one another. For example, pyrites is considered to be the enemy of the quarryman and constructor, since it decomposes with ease and stains and discolours the rock. Pyrites in sharp, well-defined crystals sometimes decomposes with great difficulty. If a crystal or grain of pyrites is embedded in soft, porous, light coloured sandstones, its presence will certainly soon demonstrate itself by the black spot which will form about it in the porous stone, and will permanently disfigure and mar its beauty. If the same grain of pyrites is situated in or near very hard, compact, non-absorbent stone, the constituent minerals of which are not rifted or cracked, this pyrites may decompose and the products be washed away, leaving the stone untarnished.

SUBSCRIPTIONS.
The CANADIAN ARCHITECT AND BUILDER will be mailed to any address in Canada or the United States for $2.00 per year. The price to subscribers in foreign countries, is $2.50. Subscriptions are payable in advance. The paper will be discontinued at expiration of term paid for, if so stipulated by the subscriber; but where no such understanding exists, will be continued until instructions to discontinue are received and all arrearages paid.

ADVERTISEMENTS.
Prices for advertising sent promptly on application. Orders for advertising should reach the office of publication not later than the 12th day of the month, and changes of advertisements not later than the 5th day of the month.

EDITOR'S ANNOUNCEMENTS.
Contributions of technical value to the persons in whose interests this journal is published, are cordially invited. Subscribers are also requested to forward newspaper clippings or written items of interest from their respective localities.

The "Canadian Architect and Builder" is the official paper of the Architectural Associations of Ontario and Quebec.

The publisher desires to ensure the regular and prompt delivery of this Journal to every subscriber, and requests that any cause of complaint in this particular be reported at once to the office of publication. Subscribers who may change their address should also give prompt notice of same, and in doing so, should give both the old and new address.

ONTARIO ASSOCIATION OF ARCHITECTS.

OFFICERS FOR 1893.

PRESIDENT	D. R. DICK, Toronto.
1ST VICE-PRESIDENT	KING ARNOLDI, Ottawa.
2ND VICE-PRESIDENT	JOHN E. BELCHER, Peterboro'.
TREASURER	EDMUND BURKE, Toronto.

COUNCIL:

AMONG the other changes of climate incident to Canada which have taken place within recent years, is the growing frequency of wind storms, the severity of which in some instances should perhaps entitle them to be called cyclones. The wind force exerted on some occasions has been sufficient to carry away church spires, and overturn buildings which were not firmly anchored to their foundations. These cyclonic storms should form a factor in architects' calculations in the future, otherwise we may expect to see the projections on many buildings, if not the buildings themselves disappear.

WE believe it would be the means of largely increasing the interest of the members in the Toronto Builders' Exchange if at stated intervals, especially throughout the winter, meetings of a social character were held. An interesting and instructive feature of the program at such meetings would be the reading of papers by members on various subjects connected with the building business, to be followed by discussion. There is without doubt the necessary talent available for this purpose, as well as to provide entertainment of other kinds. A never ending succession of business meetings is apt to become irksome unless relieved in some way by social gatherings such as we have suggested. We therefore hope to see action taken by the officers of the Exchange in the direction which has been indicated.

THE Electric Wiremens' Union and the Bricklayers' Union, of New York, are at present engaged in a dispute as to which class of workmen is entitled to cut the holes in a brick wall required to bring the electric wires into the building. On the Mutual Life Insurance Company's new building the wiremen had been doing this work themselves. The walking delegate of the Bricklayers' Union notified the superintendent that the bricklayers would strike if the work was not given to them. When this came to the ears of the Wiremens' Union, the superintendent was advised that to hand the work over to the bricklayers would mean a strike of the wiremen. As the building was not being erected by contract, the superintendent wisely decided to cease operations and give the two unions the opportunity of fighting the dispute out between themselves. It will be of interest to learn the decision of the matter, and the method by which it was reached.

THE death is announced of Col. Auchmuty, founder of the New York Trade Schools. Col. Auchmuty, who was the possessor of an independent fortune, quitted some years ago the practice of his profession as an architect and set himself to establish an institution which would afford to the youth of America facilities for acquiring a practical knowledge of the various trades. Something was felt to be required to take the place of the apprenticeship system which was fast declining, and under which the trades unions permitted only a very limited number of apprentices to be employed. The trade school which Col. Auchmuty established met the requirements of young men anxious to learn trades, and the attendance rapidly increased until it became necessary to erect more extensive buildings designed to meet the special requirements. These buildings, erected by the students themselves, stand as an object lesson in proof of the thoroughness of the instruction imparted. The schools were from the outset bitterly opposed by the trades unions, but the endowments of $130,000 and half a million dollars given by Col. Auchmuty and Mr. J. Pierpoot Morgan, respectively, have established them on a basis which will insure their future existence and usefulness.

WE lately referred to the fact that an enquiry had been received by the Dominion Government from Jamaica for ready made houses, and pointed out to Canadian builders and manufacturers that a profitable opening for business in this line might be found to exist. We now learn that Messrs. Rhodes, Curry & Co., of Truro, N. S., have embarked in this enterprise, and have recently forwarded their first shipment of houses to Jamaica. These houses require to be proof against dampness and the attacks of insects which in that country honeycomb the softer kinds of wood. To meet this requirement the manufacturers have employed Southern or hard pine. The houses are one storey in height, and in size 27 feet by 20 feet. The roof is covered by a special preparation of felt. The sides are made of panels three feet square, neatly trimmed with suitable moulding, the whole ornamented with gables and a neat cresting on the roof. Everything required in the construction of the houses was cut and fitted to its place and each piece numbered.

ITALIAN labor has of late been largely employed in the construction of railroad and other works in Canada. The Italian laborers have superseded those of other nationalities because their services can be obtained cheaper. There is, however, reason to believe that the saving to the contractor is not so great or so real as at first sight it appears. Experienced contractors assure us that Italians cannot compare with Irishmen as shovelmen. Unlike the latter they are not given to celerity of movement. We have been told of a contractor's foreman whose gang of Irish excavators was supplanted by Italians, and who was much annoyed at the lack of expedition which the latter displayed. Suddenly he bethought him of a method by which to accelerate their movements. A skillful Irish shovelman was quietly told to take his place with shovel and wheelbarrow among the Italians, and "lead them a chase." This, having no love for the Italians, he was eager enough to do. The speed at which the Italians were obliged to work in order to keep pace with the Irishman was such as they had never before experienced, and while it conduced to the contractor's profits did not enhance the friendship of the Italians for the Irishman.

THE municipal fathers of a town in northern Ontario are posing in a somewhat peculiar way as disciples of the evolution theory. It is not the evolution of the species which is engaging their attention, but the evolution of architectural ideas. Having been entrusted with the arrangements for the erection of a new town hall and market building to cost nearly $20,000, their first resolve seems to have been to avoid having anything to do with an architect. Their next step was to call in a local carpenter and ask him to prepare a rough design. Having secured this, they instructed one of the builders in the town to prepare the plans, which, on examination, met the views of some of the members of the Council but were declared by others and by the majority of the citizens to be unsuitable. In order that this important point may be satisfactorily decided, it has now been found necessary to procure the opinion and advice of an architect. It is to be hoped that the evolution theory will now be abandoned in favor of common sense methods, and that in the case of this and other works of like importance, the saving of a few hundred dollars in architects' fees will not be accomplished at the sacrifice of architectural beauty and utility.

COMMERCIAL depression seems to exist at present throughout the world. In Europe business conditions are far from satisfactory. The recent financial crisis in Australia and in the United states at the present time have laid in ruins many business enterprises in these countries, and has given rise to a widespread feeling of alarm. In the city of New York alone at the present time reports from the various trades unions show that, out of a total of 99,950 members, 36,177, or 37 6-10ths per cent, are unemployed, while the total number of unemployed workmen in the city is placed at 100,000. In the case of some trades, as for example that of plumbing, over 50 per cent. of the union workmen are reported to be out of employment. This condition of affairs across the border is likely to be accentuated in the west at least by the closing of the World's Fair a month hence. The Builders' and Contractors' Association of New South Wales decided some time since to reduce the wages of all workmen in the building trades by 10 per cent. For a time a strike of the workmen threatened to be the result, but more common sense counsels prevailed, and the reduction was accepted. Canada, too, has been passing through a time of depression, but owing to her magnificent banking system, her agricultural resources, and the absence to a great extent of the speculative spirit among her people, she has thus far escaped disasters such as have overtaken her neighbors. With the prospect of a harvest of unusual abundance, there is good reason to hope that the situation in Canada will steadily improve.

SOME interesting evidence was lately given by Mr. Stanley G. Bird, a well known master builder of London, before the Royal Commission on Labor. Mr. Bird testified that the cost of labor in the building trades had doubled within the last thirty-five years; that brickwork which then cost 40s. a rod, costs now from 80 to 90s. The surprising part of the testimony was, however, the statement that notwithstanding the great increase which had taken place in the rate of wages, the workman of to-day did not accomplish more than half the amount of work which his predecessor was accustomed to do. The witness stated that where it used to be the custom for a good bricklayer to lay a thousand bricks a day, three or four hundred is about the usual thing now. With regard to joinery the witness said, that although the workmen are given the use of machinery, the labor costs just as much as it did twenty-five years ago, when the men had to cut the stuff out of the deal, strap it up, square it up and work it. In answer to the enquiry of the examiner, Mr. Bird plainly said that the workman of to-day, instead of doing a fair day's work, does as little as he can. These statements were corroborated by a number of other builders present. While they certainly do not apply to all workmen, they are no doubt correct as regards the majority, and the condition of affairs which they reveal is far from being creditable to unionism, to the influence of which the change is chiefly due. In Canada the rate of wages has similarly advanced. As to the return given by the workman of to-day as compared with a former period, we are not in a position to speak with authority. The rise of wages alone, however, has been sufficient to largely increase the cost of building; notwithstanding, contractors are obliged to take work at lower figures than ever before. Instead of the increased cost being a charge upon the owner of the building, as it properly should be, keenness of competition necessitates that it come out of the profits of the contractor, and in many instances it is sufficient to turn profit into loss.

THERE is no more important subject that can engage the attention of the Architectural Associations of Ontario and Quebec than that of the proper education of students. By the liberality of the provincial Government of Ontario, a Department of Architecture has been established in connection with the School of Practical Science at Toronto, and the beneficial influence arising therefrom is already manifest. The Department of Architecture has been warmly endorsed and supported by the Ontario Association of Architects, and will no doubt grow in efficiency and exercise a marked influence upon the architects and architecture of Canada in the future. Unfortunately the architectural students of the Province of Quebec are at present without any means of securing instruction other than that which they may obtain by serving a term in an architect's office. While experience of this kind is most important and necessary, something more is required to equip the architect of the future to practice his profession in a manner that shall bring honor to himself and to the community in which he labors. Commendable attempts have been made to impart instruction to the students in Montreal through the medium of classes and lectures under the direction of leading members of the Province of Quebec Association of Architects, but with indifferent success. Teaching is itself a profession, and very few architects, however large the stock of information which they may have acquired, are possessed of the faculty of successfully imparting their knowledge to others. What is required is a Department of Architecture to be established in connection with McGill University. To this object we hope to see early and determined effort directed by the architects of the Province. All the accommodation which such a Department would require already exists in the splendid Technological School which has recently been erected. It only remains for some wealthy citizen to endow a Chair of Architecture and by so doing take rank among the men whose illustrious gifts have been the means of placing this University in the foremost position which it now occupies amongst the educational institutions of the world. We trust that at the approaching annual convention of the Province of Quebec Association of Architects this subject will receive the earnest attention which its importance demands.

ILLUSTRATIONS.

QUEEN'S HOTEL, MONTREAL.—A. F. DUNLOP, ARCHITECT, MONTREAL.

The building is situated at the corner of St. James and Windsor streets, near the Bonaventure Railroad depot. It is thoroughly fireproof. The walls are lined with terra cotta fireproof material, the floors and roof being constructed with rolled steel beams, filled in with terra cotta arches and strengthened with shell built angle columns. The principal interior walls are constructed of brick, and the whole façade of imported Scotch sandstone.

CHRIST CHURCH CATHEDRAL, OXFORD, OXFORDSHIRE—SKETCH BY MR. E. G. BIRD.

The accompanying sketch is a view looking towards the choir through the Lantern Tower from the North Transept. The

RESIDENCE ON BATHURST STREET, TORONTO, FOR J. R. DUNN.—HENRY SIMPSON, ARCHITECT.

earliest annals of this church date back to Saxon times and connect themselves with the almost legendary history of a renowned priory founded by St. Fredeswide, who died in 740 A. D. The Cathedral as it is to be seen now, was commenced in 1120 A. D., by Prior Guimond, and completed in 1180 A. D., and is a very interesting architectural type of the transition period between the Norman and early English styles. The roof of the choir is the work of Cardinal Wolsley in the beginning of the 16th century, and, except in size, it is one of the best and most remarkable ever executed.

C. A. AND B. COMPETITION FOR A SERVICE-PANTRY—DESIGN BY "SPERO MELIORA" (MR. ERNEST WILBY.)

COMPETITIVE DESIGN FOR ST. JOHN'S EPISCOPAL CHURCH, TORONTO—AWARDED SECOND PRIZE—J. FRANCIS BROWN, ARCHITECT, TORONTO.

COMPETITIONS.

FIVE sets of plans were submitted in the competition for plans for the improvement of St. Lawrence Market, Toronto, for which $1,000 in prizes was offered by the City Council. The judging of the merits of the designs was done by the aldermen. The first prize was awarded to Mr. H. G. Paull, the second to Messrs. Strickland & Symons, and the third to Mr. A. W. Peene, all of Toronto. The cost of carrying out Mr. Paull's design is estimated at $71,000.

LEGAL DECISIONS.

AN action has been tried in the Irish Queen's Bench Division, with the Secretary of State for War as plaintiff, the defendant being Mr. John Good, a builder, the particulars of which we find recorded in the *Builders' Reporter*. The plaintiff claimed 405*l.* damages for alleged breach of contract in regard to the proposed erection of certain buildings at the Curragh Camp Co., Kildare, and in respect of which the defendant was to receive 4,995*l.* The plaintiff alleged that it was a term of the contract that upon the expiration of two weeks from the time of receiving possession of the site the works should be commenced and proceeded with with all due diligence, so that the brickwork should be finished and the buildings roofed and completed within nine months. It was further stipulated that if the defendant failed to commence at the date mentioned and proceed in the manner agreed upon, the plaintiff should be at liberty to make any other contract for the completion of the works upon such terms as to the plaintiff should seem best, and to charge the excess of cost to the defendant. The site was handed over to the defendant in accordance with the contract, but he did not proceed with the works, and the plaintiff, owing to the default of the defendant, was compelled to make a contract with another contractor, and the plaintiff had to pay this other contractor the sum of 5,400*l.* for the works contracted to be built and completed by the defendant, being an excess of cost of 405*l.* over the amount agreed upon by the defendant.

The defence was a denial of the terms of the contract, and that it was a term of the contract that in the event of the combination or strikes of workman or other causes beyond the contractor's control the defendant should be excused and discharged from the performance of the terms of the contract. The defendant stated that he duly commenced and proceeded with the works, but shortly after the commencement a strike for an advance of wages occurred amongst the workmen and labourers employed by the defendant on the works, and by reason of the strike the defendant was prevented from proceeding with and completing the works pursuant to the contract, and under its terms he became discharged from the performance thereof. It was denied that he was guilty of any default in relation to the contract; that it was by reason of any default of his that the plaintiff was compelled to make a contract with another contractor for the building and completion of the works, or that the plaintiff had made another contract, or that he had paid to another contractor the sum of 5,400*l.* in regard to the works.

Mr. Justice Holmes submitted the following questions to the jury:—Whether the works were delayed by reason of the strikes of the workmen, and was satisfactory proof of this given to the Secretary of State for War.

The jury found for the defendant.

Send for a copy of the "Canadian Contractors' Hand-Book" (second edition). Price, $1.50; to subscribers, $1.00.

QUESTIONS AND ANSWERS.

[Readers are invited to ask through this department for any information which they may require on lines consistent with the objects of the paper. Every effort will be made to furnish satisfactory answers to all such inquiries. Readers are requested to supply information which would assist us in our replies. The names and addresses of correspondents must accompany their communications, but not necessarily for publication.]

Wilson Bros., Collingwood, Ont., ask: What is the correct weight of 1000 feet of inch lumber, maple and pine, dressed and undressed?

ANS.—The weight of undressed inch maple lumber is 4½ lbs. to the foot, and when dressed, 3½ lbs. to the foot.

"Architect," Montreal writes:—In the Province of Quebec, a considerable burden of ice accumulates on the roofs of buildings, and this must be taken into account by the architect in designing roofs. I have not been able to obtain any very definite information as to the weight of ice which would assist me in making my calculations, and would feel obliged if you could enlighten me on the subject.

ANS.—The weight of a cubic foot of ice is about 57 lbs.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.

THE semi-annual examinations for matriculation and registration of the Province of Quebec Association of Architects were held of the 27th and 28th of July. Six candidates presented themselves for examination, of whom the following four were successful: M. Helbronner, P. Sicotte, Frank Peden and J. A. Deschamps. The examiners were Messrs. A. T. Taylor, J. Haynes and A. C. Hutchison, and the examinations comprised arithmetic, mensuration, algebra, geometry and free hand and linear drawing. There were no candidates for the final examination.

The next annual meeting of the Association will be held in the city of Quebec on the 28th of September. Arrangements are not yet completed as to the proceedings, but the secretary is now in communication with the members at Quebec regarding this.

IN FAVOUR OF COMPETITIONS.*

From my point of view, it is a mistake to suppose that the profession can dispense with healthy, stimulating competitions. A man never knows what is really in him until he has measured himself with his fellows in real honest work of this kind. Consider what a large field for effort is presented to our younger men at the outset of their career, when youth, with its enthusiasm and capacity for work is so strong. With many, the commissions which they have in hand fail to fully occupy their time. Does not the opportunity thus afforded, through the medium of competitions, and which I think is confined to our profession, create, if grasped, a lasting habit of steady, continuous application and activity, a prelude to the time when hands and head will be fully occupied on more certain work.

Let me remind you of the endless opportunities which cross our path through the medium of competitive problems, for the study and investigation of the many kinds of architectural structures the architect of to-day is called upon to design. Frequently are we compelled before making a new venture, to seek, and then to thoroughly satiate ourselves with the ideas and treatment we find in the best and most successful work of perusal of illustrations, as well as by a personal inspection of their structures. Can anyone, on reflection, fail to see the helpful and lasting influences that must accrue from such a probation, even if no other advantage be the immediate outcome of the effort? How can we achieve success, if we learn no lesson from our failures? The knowledge and grasp of the requirements of any structure thus acquired, as well as the familiarising of one's self with the mind and method of some eminent specialist, probably the "facile princeps" in the particular class of work attempted undoubtedly will be a clear gain to the earnest competitor, and from my own short experience I can affirm the result will be a joyous one, and will, in the near future, bear succulent fruit. Is not the trend of some of our younger men, who look askance at competitive work, to drift into that self satisfied and crystallised state (so aptly described by Sir Joshua), from which their work ultimately becomes reduced from mere architectural barrenness, to the poorest of all imitations—having to repeat what they have before often repeated.

We may love and reverence the past as archæologists, but, as architects, let us not forget that archæology is the bone of living progressive Architecture, and if our art is ever to evoke popular enthusiasm it must do so by embodying the thoughts, the aspirations, and the genius of the living people for whom we build.

There is one more thought so intimately connected with the whole question, viewed from the professional side, that I think it ought not to be passed over without comment, however brief. It is the deplorable preponderance of misdirected effort competitive work produces. One is confronted in almost every competition with the melancholy sight of many very meritorious architectural productions, possessing picturesqueness of grouping, excellent proportions, combined with artistic and well-designed detail, yet having all chance of their success nullified by the utter unsuitability of the design, and which is frequently mated to an indifferent and ill-considered plan. These artistic and impractible productions are greeted with the admiration both of the profession and the general public, but, alas! command nothing more substantial. Those who allow their prolific pencil to have the upper hand—resulting not infrequently in relegating to quite a secondary consideration the actual needs and inexorable stipulations of "Competitive Instructions" given for their adherence, and who prefer to follow the bent of their own sweet will and pleasure—are only amusing themselves. It is misapplied energy, and any chance of probability there is of their clever but impracticable design being chosen, becomes merely a "vision of their own romance."

With regard to the etiquette aspect of competitions, there is still floating about, even among many practising architects, who on other matters are not without intelligence and discernment, that strange notion that to be engaged on competition work is somehow derogatory from a professional point of view. These men (who ought to know better) carelessly deprecate in very doubtful taste the praiseworthy efforts made by their more enthusiastic and energetic fellows, through this medium presented to them. I feel very confident, indeed, that those who look with lukewarmness, if not with absolute hostility, on the many opportunities thus open for the obscure professional man, probably, as Gray has it, "A youth to fortune and to fame unknown," to further his advancement and to ultimately achieve success, have really never been reasoned into the position and attitude they take.

In the first place, by this method, a strong belief and advocacy in the policy of universal "Free Trade" is shown, the soundness of which, I venture to affirm, no one will be prepared to question, and thus is secured by the market the privilege of purchasing in the open market. Liberty also is afforded for any qualified practitioner to dispose of his wares (*i. e.*, the prodnct of his brains and skill), wherever that kind of merchandise is in requisition, and thus a wide field of additional opportunity and usefulness is opened out to us, and which may largely conduce to the greater prosperity of our profession. Again, the competitive system is largely instrumental in bringing about an entire immunity from those petty jealousies which we all deplore, but which are frequently experienced in many provincial towns, where several practitioners are about equal in status, professionally and socially. If competitions be framed and conducted on strictly equitable lines (which is of paramount importance, and to which I shall shortly refer), then the spirit of emulation being stirred, each competing architect is dependent entirely on the merit of his effort, and not on the number and the influence of his friends; then it follows that the discreditable and unprofessional touting, which is greatly to be deprecated, but which, alas! is only too frequently resorted to, at once ceases, and a more honourable and equitable state of things is adduced.

There is one other advantage I should like to point out that the public obtain through their encouragement and adoption of competitive work. It is the benefit of having any contemplated architectural project attacked by a number of distinct minds, and the results submitted for their inspection and choice. Frequently one's attention is arrested, whilst inspecting competitive designs, by some that exhibit a freshness of conception, an originality, and a boldness that doubtless has been drawn out by their authors zeal to excel, and which, I venture to state, would not be obtained through any other agency. No more being attempted than is done, but a faithful performance of what is undertaken to be performed.

Many of us will recall with pain the heartburning and strong sense of indignation we have been occassionally subjected to by a flagrant deviation from rectitude and fair dealing on the part of the promoters in some competition, into which we have been cajoled to enter the lists. The indifference displayed by such unscrupulous people to the inexhaustible patience, time, and labour that architects have fruitlessly given, is so inconceivably deplorable that it will hardly bear discussion. The question as to how this particular evil is to be remedied forms part of a larger question affecting the whole subject. But are we not all "masters of our fates"? Does not the blame for such a state of things chiefly rest with ourselves, and have we not the remedy mainly in our own hands? It is invariably the case that in these "questionable" competitions, neither are the "instructions, drawn up" on lines suggested by the Institute, or by some practitioner (a man of repute), nor is any mention made in same as to the promoter's intention to call in a professional man to advise them in arriving at a decision. With these very ominous omissions clearly before us, it is our duty to our profession, as well as to ourselves, to leave all projects framed on such doubtful lines severly alone, and I for one shall gladly welcome the day when every practising architect shall consider it his duty as well as his privilege to become a zealous and enthusiastic supporter of the Royal Institute, thus further to strengthen its hands by which alone it can successfully cope with some of the disabilities we still have with us.

* From a Paper read before the Manchester Society of Architects.

An action has been entered by the management of the Dominion Bank with the object of preventing the Baldwin Estate from building upon a light area on the west side of the bank building on King street, Toronto. It is claimed that the lease of the land on which the bank stands covers also the area.

ORNAMENTAL TREATMENT OF IRON.*

IRON has great cause to be dissatisfied with the mode of ornamental treatment it has received. Its special qualities as a building material have conferred such general advantages that it is a matter for regret we do not pay the attention to its appearance that we give to it in its purely useful capacity. The generous aid which it lends to us in the solution of our building difficulties and the manner in which, by its use, we are enabled to do so much that was hitherto impossible, surely demands that its worth shall cease to be covered by imitative and unsuitable designs. Who is the engineer or architect that has not had reason to be thankful for its aid, perhaps as a girder in getting over a troublesome span where intermediate supports would have been objectionable; or by its use as columns in the little lateral space taken up in proportion to the work done, and where by reason of its bulk stone would have been inadmissible, and in return the mean action is taken of covering up the iron girder with wood and cement, and by painting and sanding, making it look like a stone lintel, which could never have done the work. Or in the case of a column, by moulding it after a Classic model, totally ignoring the very palpable fact that by its lean shaft all the proportions of the model are lost. On no account should any of the Classic columnar Orders be applied to it, for if enough of iron is used to retain the usual proportions waste of materials is bound to occur, and, on the other hand, if the use is made economically the ratio of thickness to height is sure to result in a sickly and lean effect. The advantage of iron is that it enables us to do the work required with much less bulk than if stone, brick or wood were used; therefore it is contended that it is contrary to the ethics of good design to make it appear like those materials when doing its superior work. In the case of the girder or truss surely there can be no logical objection to their straightforward exposure. The rivets and the L irons could easily be left to make a presentable appearance. An example of a girder exposed is to be found in the front of a recent large building erection in Sydney, and it must be admitted that its calm, dignified and straightforward appearance is not unpleasing. The flanges and L. irons have been carefully worked, and the heads of the rivets left very clear; but beyond this there is nothing in the way of ornamentation, and none is wanted, for where it has to do laborious work a simple but effectual appearance is the best, and it would be entirely out of place fancifully to ornament it. Deference must of course be paid to the necessity for sheathing the iron columns and girders with fire-resisting material; but this is not always necessary, for there have been one or two examples of iron columns and girders so constructed and arranged that by means of a fusible plug in case of a fire, a continuous stream of cold water will circulate throughout them, provision also being made that all cradles and seating should have similar benefit; and an able paper was read before the Engineering Association of New South Wales touching on the subject, which will be found in the *Proceedings* of that Institute for 1892. Wrought iron is capable of lending itself to very delicate and artistic treatment, and recourse to it should always be taken to give the necessary contrast to the heavier and more substantial construction. Gates, grilles, railings, finials, etc., are excellent chances to treat in a light way, and the most beautiful results can be obtained. Every designer can appreciate the addition to the proportions of a building which a raised and curved roof makes, and the strength and pliability of wrought iron in every way conduces to the easy attainment of such roofs. Sir Gilbert Scott in *Gothic Architecture, Secular and Domestic*, expresses the opinion that "there can be no doubt that the iron roof is susceptible of exquisite beauty." And it would indeed be difficult to prove the contrary. But unfortunately it is seldom that even an attempt is made to gain such a result. It is, however, in its cast state that most of the anomalies exist. At the present there is a term—"cast-iron impudence," which is freely used, and actually it might be suggested that it had its origin in the glaring and impudent manner in which cast-iron ornament is plastered over our buildings. It is not going too far to say that almost 80 per cent of recent erections in the colonies have in some way been made to rely on this stuff for appearance, and yet at the same time it would be impossible to find more than about six different designs amongst the whole. In every city and town is to be found the cast-iron shop, the keeper of which has set out on the walls the same monotonous display of specimens to be found in every other place of a like nature. He calls each design by some fanciful but totally inappropriate name. He sells it by the foot, it is put up by the foot and the result is a never-ending array of yard after yard of cast-iron, soutterly bereft of any variety or beauty as to be positively offensive to a tasteful eye and totally stamp out even a spark of regard for cast-iron. It is not only the want of variety or beauty in the design, but also the roughness of the casting, no care being taken to preserve a good surface or sharp edges; and the casting very often appears a confused mass of dots and lumps. It must not be thought that the purpose of this paper is to entirely condemn the principle of treating it for ornamental purposes; but some improvement might be made with advantage in the habit of making in cast-iron an attempt to resemble, for instance, ferns or other vegetable forms. Cast-iron should not be used for purposes of ornamentation only, but rather primarily as meeting a necessity and then ornamented to make presentable. As an instance, might be taken a column in a store, the plain shaft of which together with a simple and unostentatious cap merging in a cradle with bracing studs, is far better and more in place than to have an elaborate thing in Corinthian style put in somewhere in the front, with no other reason for its existence than that it is intended to make a nice appearance; or again, would it not be far better to just have a little, but suitable wrought-iron work, judiciously used, than all the cast-iron fringes, crests, brackets and finials, which are so unmercifully used? Cast-iron is best used only when compressive strain is to be resisted, and in such cases it should be very unostentatiously beautiful. If used only for ornamental purposes the greatest care should always be exercised not to indulge in an excess which is so tempting on account of the ease with which such is produced. All materials which allow of being moulded or cast, and thereby easily multiplied, conduce to quantity in large proportion, to trouble in production, and human nature is so fond of display that the inevitable result is over bearing and debased ornamentation; not so much the consequence of itself in its parts being bad, as because of being in direct violation of the rule—"that of the best we may have too much."

* From a paper by Mr. Jas. Mangle, read before the Engineering Association of New South Wales.

MONTREAL.

(Correspondence of the CANADIAN ARCHITECT AND BUILDER.)

A decision has just been rendered by Judge Delorimier of the Superior Court upon a novel and important point. Mr. Alex. Hurtubise, against whom the late Mr. J. J. Brown, architect, brought action for $30,000 damages for injuries sustained by being run over on the public highway, petitioned for an order to compel deceased's family to allow an autopsy to take place, the petitioner's contention being that such an autopsy would reveal the fact that Mr. Brown died of diabetes, and not from the injuries received. The judge refused to grant the petition, on the ground that although Mr. Hurtubise had a real interest in the matter, still the court could not take upon itself to protect an individual interest by violating the general principle which makes the home of each family a castle that must be respected in its sanctity and privacy.

A movement is on foot to have a boulevard constructed of the width of 150 feet from the market on St. Lawrence Main street to St. Denis street, with the Monument Nationale at one end and the new Laval University building at the other.

A recent examination by the Inspector of Buildings revealed the fact that the spire of St. Andrew's church has shifted about six inches in a northeasterly direction. In consequence steps have been taken to anchor it more firmly.

Thomas Evans and Edward Reil have registered to carry on business as general contractors.

Upwards of $200,000 is said to have been expended last year in making extensions and improvements to hotel buildings in this city for the purpose of accommodating the crowds of visitors who were expected to stop over here en route to or from the World's Fair. The crowds have failed to put in an appearance, and the hotel owners are lamenting their fate.

Death is rapidly thinning the ranks of senior Montreal architects, three of whom have been called away within the last year. The last to be cut down was Mr. John James Browne, who died at his home in this city at an early hour on Thursday, the 3rd inst. Mr. Browne received serious injury by being knocked down by a horse and sleigh on the street in Montreal last November, and although for a time he rallied, the accident appears to have induced an attack of Bright's disease to which he eventually succumbed. Mr. Browne was born in the city of Quebec on the 12th of October, 1837, and was educated at the High School in that city. He began the practice of architecture when nineteen years of age, and obtained second and first-class certificates as the result of a post-graduate course under the celebrated engineer and architect, Lord Russell. He had an extensive practice in this city and province. He was elected a member of the Council of the Province of Quebec Association of Architects at the last annual convention. He was also a member of the Montreal Board of Trade and a Justice of the Peace. A wife, three sons and three daughters are his survivors.

LONDON.

(Correspondence of the CANADIAN ARCHITECT AND BUILDER.)

A well-known contractor of this city writes: I observe in the London correspondence of the ARCHITECT AND BUILDER for July the statement that there is a good opening in this city at present for outside contractors, owing to the limited number of bidders and the large amount of work in progress and projected. Your readers are told that for want of competition the cost of buildings is maintained at such high figures as must tend to retard building enterprise. This is far from being a correct presentation of the situation in this city. The facts are that at present the number of resident contractors is more than sufficient to provide active competition in tendering for all contracts. As regards prices, they are barely sufficient to cover the cost of the work and leave a slight margin of profit to the contractor. Surely it is not desired that contractors should work for nothing. An attempt is being made by some of our local architects to introduce some of the features of modern American architecture into their designs, especially in residence work. The local contractors not having had experience with work of this class, do not know with any degree of definiteness what the cost of execution may be. In submitting tenders, therefore, they increase their bids for this class of work as compared with the work to which they have been accustomed, to the extent which they deem necessary to cover the extra cost of its execution. This is all the foundation that exists for the statement that prices have advanced or are higher than usual.

HAMILTON.

(Correspondence of the CANADIAN ARCHITECT AND BUILDER.)

Mr. George Webb, a well-known builder of this city, was recently summoned before the courts at the instance of the Building Inspector, on a charge of violating the city building by-law. The offence alleged consisted of covering with wood instead of metal the tower of a church building. Mr. Webb showed that the wood covering of the tower was cased with brick, whereupon the magistrate dismissed the case.

The expenditures of the Board of Works have already exceeded the appropriation by the sum of $10,000.

The residence of Mr. James Balfour, architect, was recently ransacked by burglars.

The significant statement appears in one of the daily papers that while the building permits for a given month aggregate $57,675, the actual building operations have been much more extensive. In other words the building by-law, which requires a permit to be obtained prior to the commencement of every building, is not enforced.

HANDY TABLES OF DIMENSIONS OF JOISTS AND RAFTERS.

FOR ready use in the office the following tables, submitted by H. Maack, Principal Academy of Architecture and Building, St. Louis, through the *Southern Architect*, will be found practical and time saving. No development of formula is required, but simple multiplication of the clear span in feet by the factor hereafter given will give the desired width of joists or rafters for any span for 2″ joists. For 2½″or 3″ joists, it will be required to use the formula, but in the common buildings 2″ joists are generally used and the free bearing length or span can be readily taken from the plans. It will therefore only be necessary to find the varying width or breadth, and this will vary according to the load or span.

The tables are computed from the formula:

$$h = \sqrt{\frac{p \times l \times 3}{k \times t \times 4}}$$

in which the letter

h = height, breadth or width of joists or rafters in centimeters.
l = length or span of joists or rafters between support in centimeters.
t = thickness of joists or rafters in centimeters.
k = safe load, for yellow pine 60 kg., and for white pine 50 kg. per square cm. of section area, with a safety factor of 10.
1 kilogram (kg.) = 2.2 pounds
1 meter (m) = 3′ 3⅜″ = 3.28 feet = 100 centimeters (cm.) = 1000 millimeters (mm.)

TO FIND THE BREADTH = H.

For ready use of the tables the value "l" is already transformed into feet, and the clear span or length of joists or rafters between supports = l, must be used therefore in feet only.

OWN WEIGHT OF CONSTRUCTION, AS JOISTS, CEILING AND FLOORING.

Per square foot—2″ × 10″ joists—16″ to center 12 lbs., 12″ to center 15 lbs.

Per square foot—2″ × 12″ joists—16″ to center 15 lbs., 12″ to center 18 lbs.

Per square foot—2″ × 14″ joists—16″ to center 18 lbs., 12″ to center 20 lbs.

Per square foot—2″ × 6″ ceiling joists and 1″ plaster and lath, 16″ to center 15 lbs.

Per square foot—horizontal measurement of roof, including wind and snow, 50 lbs.

The loads given in the tables include the load of the construction.

TABLE I.

FOR DWELLINGS AND FACTORIES USING LIGHT MACHINERY.

Supposed load on the square foot floor space = 80 pounds.

2″ joists 16″ to center; h = 1 ft. × .75 (¾)″ yellow pine or × .8 (4-5)″ white pine.

2″ joists 12″ to center; h = 1 ft. × .66 (⅔)″ yellow pine or × .7 (7-10)″ white pine.

TABLE II.

FOR STORES.

Supposed load on the square foot of floor space = 110 pounds.

2″ joists 16″ to center; h = 1 ft. × .9″ for yellow pine.

2″ joists 12″ to center; h = 1 ft. × .77″ for yellow pine.

TABLE III.

FOR DANCING HALLS, HAY AND FRUIT STORES.

Supposed load on the square foot of floor space = 150 pounds.

2″ joists 16″ to center; h = 1 ft. × 1″ for yellow pine.

2″ joists 12″ to center; h = 1 ft. × .9″ for yellow pine.

TABLE IV.

FOR SALT WAREHOUSES AND WORKSHOPS USING HEAVY MACHINERY.

Supposed load on the square foot of floor space = 175 pounds.

2″ joists 16″ to center; h = 1 ft. × 1.13″ for yellow pine.

2″ joists 12″ to center; h = 1 ft. × .98″ for yellow pine,

TABLE V.

FOR GRANARIES.

Supposed load on the square foot of floor space = 200 pounds.

2″ joists 16″ to center; h = 1 ft. × 1.2″ for yellow pine.

2″ joists 12″ to center; h = 1 ft. × 1.″ for yellow pine.

TABLE VI.

FOR WAREHOUSES IN GENERAL.

Supposed load on the square foot of floor space = 220 pounds.

2″ joists 16″ to center; h = 1 ft. × 1.25″ for yellow pine.

2″ joists 12″ to center; h = 1 ft. × 1.1″ for yellow pine.

TABLE VII.

CEILING JOISTS.

Supposed load of construction, *i. e.*, joists and plastering = 15 pounds per square foot.

2″ joists 16″ to center; h = 1 ft. × 24″ (¼)″ yellow pine, or × 3 (¼)″ white pine.

2″ joists 12″ to center; h = 1 ft. × ¼″ white or yellow pine.

TABLE VIII.

FOR RAFTERS OF FLAT AND HIPPED ROOFS.

Supposed load on the square foot horizontal = 50 pounds; this includes the construction, snow and wind loads. Measurement taken from roof plan, independent of slant of roof.

2″ rafters 24″ to center; h = 1 ft. × .6381 (⅔)″ for yellow or white pine.

2″ rafters 20″ to center; h = 1 ft. × .583 (3-5)″ for yellow or white pine.

2″ rafters 16″ to center; h = 1 ft × .5 (½)″ for yellow or white pine.

Collar beams must be inserted for hipped roofs, if rafters are longer than 12 feet; make same one-half the thickness of rafter, but the same width.

APPLICATION OF THE TABLES.

1st Example.—In a dwelling where joists have a clear span (l) = 16 feet, What is the proportionate width (h) for yellow and white pine, for 16″ to center and for 12″?

1st Answer.—16″ to center, yellow pine considered; Table I., shows for h = 1 × ¾″ = 16 × ¾ = 12″. Thus 2″ × 12″ yellow pine joists placed 16″ to center would answer our case.

2nd Answer.—12″ to center, yellow pine considered; Table I., gives h = 1 × .66″ or 1 × ⅔″ = 16 × ⅔″ = 10⅔″. In this case 2″ × 10″ yellow pine would suffice, spaced 12″ to centers.

3rd Answer.—16″ to center, white pine considered; again taking from Table I., our factor given for white pine 16″ to centers we find h = 1 × .8″ or 4-5″ = 16 × .8″ = 12.8″; therefore 2″ × 12″, although a little weak, will do.

4th Answer.—12″ to center, white pine considered; Table I., shows us h = 1 × .7″ or 7-10 = 16″ × .7″ = 11.2″; 2″ × 12″ should be used, 12″ to centers.

We should not forget to arrange one row of cross-bridging for every 7 ft. of span. In case we get results like answers 2 and 3, one additional row of bridging will make up for the fraction of an inch we neglect to make use of the nearest stock-joists. The bridging does not increase the strength of the joists, but mainly acts to hold them upright and from turning over sideways. In a later paper we will see how bracing with 1″ strips will increase the strength, sometimes employed for wide spans and when the time is too short to get special thicknesses cut by the mills.

2nd Example.—Find the dimensions of ceiling joists required for the span of 15 feet.

From the Table VII. we obtain the formula:

h = 1 × ¼″ yellow pine, or 1 × ⅓″ white pine, 16″ to centers; *i. e.*, 15 × ¼″ yellow pine, or 15 × .⅓″ white pine, 16″ to centers.

Thus 2″ × 4″ yellow pine, or 2″ × 6″ white pine would be right. If we try on 12″ centers, Table VII. shows h = 1 × ⅓″ for white pine = 15 × ⅓″ = 2 × 4″ white pine, 12″ to centers will answer this case satisfactorily.

3rd Example.—A hipped roof ½ pitch; find the rafters required. Table VIII. is needed. We find 1 × ⅔″, or 1 × 3-5″, or 1 × ½″ for the distance to centers, of 24″, 20″ and 16″ respectively. The house may have a width of 26 feet. To find the length of the rafters we use the Theorem of Pythagoras. "In a right angled triangle the longest side (hypothenuse) is equal to the square root of the sum of the squares of the two small sines," or $c = \sqrt{a2 + b2}$, developed from $c2 = a2 + b2$, where c = the longest side or hypothenuse, a and b the other two small sides (catheti.)

In our example ½ of width of the building = ½ of 26 = 13 feet is one cathetus and the other also 13 feet by ½ rise roof; thus the formula $c = \sqrt{a2 + b2}$ becomes when b = a, $c = \sqrt{a2 + a2} = \sqrt{2a2} = a\sqrt{2}$. This last expression is convenient if a is an irregular number, for the $\sqrt{2}$ is found in most any hand-book like Kidder's on page 8; gives: $\sqrt{2} = 1.4142$, this × a (= 13) = 18.38 feet length of rafters. The formula $c = \sqrt{2a2}$ would have been more convenient here for 2a2 = 2 × 13 × 13 = 338 and the $\sqrt{338}$ = 18.38 ft. found on page 13 of Kidder.

If only an approximate answer for the length of rafters is desired, which would fully satisfy our figuration, we may use the improper fraction 7-5 and multiply one, the equal small sides of our right-angled triangle, thus: 7-5 × 13 = 91-5 = 18 1-5 ft., near enough for our purpose, as we take only the nearest full feet (18) into consideration. h = 18 × ⅔″ = 12″, or 2″ × 12″ rafters, 24″ to centers. h = 18 × 3-5″ = 10 4-5″, or 2″ × 10″ rafters, 20″ to centers. h = 18 × ½″ = 9″, or 2″ × 8″ rafters, 16″ to centers.

The rafters being over 12 ft. in length, it will be required to insert collar-beams. If we get sufficient tie at the foot of the rafters to the joists, we may design the collar-beams 8 ft. above floor. On supposition that outside wall and top of rafter meet in floor height, we obtain the length of the collar-beams as follows: Whole height of roof 13 ft., less 8 ft to bottom of collar-beams = 5 ft. multiplied by 2 = 10 ft., the length of the collar-beams; for twice the rise = span by ½ pitch roofs. This last holds good in this particular case only, but proportion will solve it under all circumstances. Entire height to entire span as is partial height to collar-beam, *i. e.*,

$$13 : 26 = 5 : X$$
$$X \times 13 = 5 \times 26$$
$$X = \frac{5 \times 26}{13}$$
$$= 10 \text{ feet.}$$

PERSONAL.

Mr. Chas. A. Bradshaw, a well-known Toronto builder, died on August 5th, age 54 years.

Mr. J. A. Ellis, architect, of Toronto Junction, has lately returned from a visit to the United States.

Mr. Thomas Smarr, a well-known and respected builder of the city of Toronto, died on July 14th.

Mr. Ernest Wilby, who has spent the last two years in the study of architecture in England, has returned to Toronto.

Mr J. W. Gray, architect, of Toronto, was severely injured a fortnight ago by being thrown from a carriage at Brantford.

Mr. John Wilcox, builder, who had been a resident of Toronto for half a century, died at his residence in that city a couple of weeks ago.

Mr. Fuller, Chief of the Department of Architecture at the Dominion Capital, is enjoying with his family a period of relaxation in the lake district near Peterboro', Ont.

Col. Charles G. Otis, of the Otis Bros. Co., manufacturers of elevators, died at his residence in Brooklyn, on the 7th inst., age 62 years. Col. Otis had been in feeble health for a year or two past.

Mr. Richard M. Hunt, of New York, received from the hands of the President of the Royal Institute of British Architects, on June 19th, the Victoria Royal Gold Medal awarded him by the Institute some months ago.

SANITATION AND HEATING.

EFFECTIVENESS OF HEATING APPARATUS.

THAT there is a wide difference, as pointed out by the *Building Register*, in the effectiveness both of hot-water heating and steam-heating apparatus is a fact known to all well-informed men engaged in the heating trade, but in many instances this difference is accounted for by referring it to anything but the proper cause—namely, defects in the system of piping between the steam boiler or water heater and the radiators. The boiler may be good, the radiators may be the best in the market, yet the result is unsatisfactory. In most such cases it will be found that not enough study and care have been given to arrangement of pipes and radiator connections, to their proper sizes with reference to the surface they are to supply, to their pitch, to the supply in steam-heating pipes of proper relief pipes, to avoidance of traps in pipes, to provisions for expansion under the action of heat, and so on to the end of the chapter. These remarks apply to both large and small installations. Some of these defects are not always chargeable to the contractor who puts in the apparatus. Many buildings, large and small, can be found wherein, when first erected, the heating apparatus worked excellently, but in a year or two began to snap and pound vigorously, while its lack of vigor in heating some parts of the building became uncomfortably apparent to complaining occupants. What has happened during the interval between satisfactory testing and the failure to heat successfully is that the building has settled unequally, thus neutralizing, and in many cases often reversing, the inclination given by the fitter of the pipes and canting radiators so that their outflow connections are higher than their inlets. Examine the boiler; you will find there nothing to prevent efficiency. Radiators and valves, water-feeding and draft-regulating appliances may be all in first rate working order. The fault is that the piping has been disarranged because the building has settled, and settled unequally.

DIRECT-INDIRECT RADIATORS.

OUR German exchanges advertise something which seems to us, says the *American Architect*, to be worth the attention of architects and designers here, in the shape of direct-indirect radiators, formed, not of vertical tubes or castings, as is usual with us, but of horizontal coils. The idea is not new. We have ourselves employed the same arrangement, and have seen it used by others, but the fact that a manufacturing house finds it worth while to make and send out such coils in large quantities suggests the probability that, with a little study, coil radiators might be made with castings put together with bolts as vertical radiators now are, which would heat better, particularly for direct-indirect systems, and be more ornamental. It must be confessed that, so far, no beautiful objects in the shape of vertical radiators have made their appearance in the market. We do not say that they cannot be made, on the contrary, it is possible that a delicate colonnade design might be successfully adapted to such radiators; but the surface-ornamentation hitherto employed has only increased the desire of architects to conceal appliances of the sort as much as possible. With coils, it seems to us that much more might be done. In the German examples, the coil is a flattened spiral, the fresh air introduced from out of doors being brought up through the middle. This is a good shape for circulation, as well as for heating. It is well known that horizontal coils heat much more air, for a given surface, than vertical tubes, and it would be easy, in a cast radiator on this system, to arm the hollow interior of the coils with pins, which must increase their efficiency.

A new hospital building has recently been completed in Owen Sound from the plans of Mr. J. Forster, architect, of that town. Accommodation has been provided for seventy patients and the necessary staff of attendants. The building, which cost $10,500, is three stories in height with a basement, and is constructed of brick. Mr. Alex. Greene was the contractor.

DECORATION AND FURNITURE.

ON SOME OF THE ARTS ALLIED TO ARCHITECTURE.

MR. WALTER CRANE, in an excellent paper on the above subject, says:

I fail to see how any art can be wholly taught or learned on general principles, since it is of the nature of art to address itself to particular problems, the conditions of which constantly vary. Certain general principles have been evolved out of collective practice of more or less value no doubt in a general way, but they must always be liable to qualification in their adaption to particular cases.

Nothing of the nature of art can be formulated as an exact science, happily, or the limits of its invention and variety would soon be reached. Art, however, has its scientific side, though the science of art is not exactly scientific or theoretic, but practical, and rather consists in recognizing particular necessities of conditions and materials, and the realizing that the frank acknowledgement of the nature of these conditions and materials leads in all the varieties of design, in association with craftsmanship and architecture, to the highest beauty.

The peculiar beauty of a stained-glass window, for instance, is entirely dependent upon this frank acknowledgement of conditions. A screen of transparent color, a pattern defined and united by leads and held in position by iron bars. Directly any attempt is made to overstep its natural limits—to make it look like a painted picture, to get chiaroscuro and vanishing points, or try to ignore the leading as an essential condition of its existence, the charm and joy of it is lost. There is a distinct character and beauty both in plain-leaded glass, throwing a pleasant network of simple geometric lines over the blankness of window panes. Henry Shaw, in his glazier's book, gives a great variety of delightful leading patterns.

Now, any design for a colored-glass window should, in the first place, be a good arrangement of lead lines, I think, a good pattern in short, whether figure subject or not; and, secondly, a good pattern considered as an arrangement of color or jewelled light.

The artistic designer and maker of a wrought-iron gate, grille or railing, whatever phantasy he might introduce, would never forget the essential requirements of a gate, grille or railing. He would never forget the architectural relation of his work, or rather he would make the chief beauty and inventiveness of his treatment of wrought-iron spring out of that relation.

The practice of modelling in clay designs intended to be carved in wood has, it seems to me, been most destructive of the beauty and character of true wood carving. The same may be said of stone and marble; the essential spirit and go of the thing, the characteristic touch and treatment with each material, in which the designer works, claims as its own, and which is its own particular reason for existing—these are, of course, lost, or turned out of recognition when a copy is made of something already existing in a material and produced by a method totally different.

Much better keep to simple mouldings and plain paintings than bring in ornament which has no character or meaning of its own. We must not confuse the mere spreading of ornament with decoration in its true sense, for design in all its forms may be said to be governed by an architectural instinct of its own, which makes it a harmonious part of the building with which it is united, and which unites it, and puts it in harmony with itself.

William Morris, in calling attention to the work of the designers of the past, recognizes the subtle sense of truth and simplicity, the delight in the beauty of nature around them, which was a perpetual tonic to the toil-pressed craftsman, and without which, no art, past or present, can have meaning or endurance. He says, speaking especially of early Persian art, which in its best development, was decorative art: "In their own way they meant to tell us how the flowers grew in the gardens of Damascus, or how the hunt was up on the plains of Kirman, or how the tulips shone among the grass of the mid-Persian valley and how their souls delighted in it all, and what joy they had in life; nor did they fail to make their meaning clear to some of us. One who has devoted much attention to the study of Greek art, lately remarked on the relation maintained in this masterpiece of mural sculpture between the relieved figures and the ground space; each piece of relief is balanced by an empty space of the same extent, though, of course, different in shape, so that could the *relievo* be compared with the *basso* in the whole design, they would be found to correspond in extent."

PUBLICATIONS.

The name and good-will of *Metal*, of New York, have been sold to Mr. David Williams, who will amalgamate the paper with the *Metal Worker* and the *Iron Age*.

Messrs. S. E. Hendricks & Co., 54 Broadway, New York, have just issued the third annual edition of "Hendricks' Architects' and Builders' Guide and Contractors' Directory of America." The book contains nearly 700 pages and 170,000 names and addresses arranged under 800 classifications. It appears to have been compiled with care, and should prove valuable to architects, manufacturers and supply firms.

LIFTING UP A MASSIVE BUSINESS BLOCK.

THE World's Fair is full of wonderful sights, but it contains nothing so amazing, so thrilling to an observer, or more interesting to the builder, than the scene on Monroe street, Chicago, where a massive stone and brick business block is being raised up bodily a distance of fourteen feet for the purpose of interposing an additional story. The building measures 50 x 106 feet, is six stories in height. The thickness of the walls was inadequate to support an additional story above, and the only alternative was to interpose one story at the ground level, the foundation being sufficient to carry one additional story.

The weight of this building above and including the main floor was found to be 11,440,000 pounds or 5,720 tons, in round numbers twenty-seven pounds to the cubic foot. There are used in the raising of this building 1,800 three-inch jack screws. To operate these screws 132 laborers are required, each one having charge of from eight to twelve screws. At a given siginal on a shrill whistle each man, with an iron bar four feet long, gives each screw a one-quarter turn. The pitch of the screws being five-eights of an inch, each one-quarter turn raises the building three-sixteenths of an inch, and it is found that the immense load of 5,720 tons can be raised three inches an hour. When the screws have been turned from their blocks twelve inches, new support is required, which is secured by a blocking of 6x6 inch timber. The screws, which are twenty-four inches long, are then slackened, the load placed upon the new blocking and the screws set for another turn. At no time is there more than one of the group of twelve screws without a load.

Experience has proved to these self-taught screw engineers that the limit of weight at any time given to one screw should not exceed five tons, although it is known that a strong man with a four foot lever can raise three times this amount. An experiment was once tried as to the breaking strength of one of these screws and it was found that the flange which supports the screw, broke at the extraordinary weight of fifty-four tons. The weight of the building being 5,720 tons and there being 1,800 screws, the proportion of the weight upon each screw is three tons, so that the factor of safety in this piece of work is about eighteen. During the raising of this building careful records are taken and frequent measurements are made to ascertain whether or not the building is raised perpendicularly from the point from which it started. Should any laborer neglect to give the proper turn to the twelve screws under his charge, the result is at once shown by these measurements. This system also insures the exact vertical raising of the building, assuming, of course, that it starts from a level surface. As soon as the building is raised to the intended height—14 feet and 8 inches—the work of building up with steel columns and girders and masonry will be commenced and the building lowered onto its new supports; the interior will then be completed as in an ordinary work.—*Stone.*

TIN ROOFS.

THOSE who are interested in the subject of free trade versus protection duties will find an interesting problem for solution in tin plate and its application for roofing purposes, writes Arthur Seymour Jennings in the *Plumber and Decorator*. Probably one-half of all the roofs in the United States of America are covered with tin plate. Most of it is made in Wales, is exported into America, and a duty is exacted. The subject of tin plate has been discussed at length in the papers, especially in connection with the notorious McKinley tariff; and buckets full of ink have been wasted in trying to arrive at a clear understanding as to whether the American Government are best serving the people in taxing an import so widely used, considering that the material is not made at all in the States, or at least to any extent. Our readers may be familiar with the fact that there have been one or two attempts to start tin plate factories in the States by the aid of workmen obtained from England.

But it is not to enter into a question of tariff that this article is written, but rather to call attention to the somewhat remarkable fact that tin plate, although made at home, is not used at home for roofing purposes. That it forms a very economical roof-covering, the first cost of which is low, and the durability of which is considerable, will readily be conceded by those who have had an opportunity of examining it in use. Why then should it not be used in England? Of course, it can only be applied to roofs that are comparatively flat, but then we have very many flat roofs that are covered with zinc, sheet lead, or copper.

At first thought a number of objections to the use of tin plate will suggest themselves. It may be said that it would not stand the climate, that flat roofs are objectionable in any case, and that even zinc roofs are more frequently in bad order than they are in good. In answer, we may point out that the climate of the United States is much more severe than that of England. In few localities east of the Rocky Mountains is the temperature less than 100 degs. sometimes in summer, or more than several degrees below zero sometimes during the winter. Broadly speaking, it may be said that anything that will stand the climate of America will prove durable in England. This is leaving out certain limestone and other materials that are likely to be injuriously affected by the action of sulphuric acid contained in the air when large quantities of soft coal are burnt, such as is the case in English cities.

Flat roofs are, of course, objectionable, but they are nevertheless a necessity, and if they are to be covered the main object is to render them permanently watertight at the lowest possible cost. The writer claims that this can best be done by the use of tin plate.

As to the durability of tin roofs. When properly laid and painted periodically, they last certainly as long as zinc, in fact, it is claimed that, if the painting is done every second year, they will last indefinitely. The tin is laid without rolls, and usually without laps, the joints being simply soldered together. The usual flashings to the wall are provided, but that is all.

The durability of a tin roof depends largely upon the paint. In the best roofs the under surface of the tin is painted with a single coat and the upper surfaces with three coats. Before the paint is applied any resin adhering is scraped off, and then the whole of the surface is washed clean with benzine to make it entirely free from grease. Some roofers allow the tin to become rusty before applying the paint, on the theory that this will afford a better hold. This practice is, however, entirely objectionable, because the rust once started continues. The cost of painting is not large as a cheap paint is used, made principally of oxide of iron or metallic brown. The application of it does not require the employment of particularly skilled labour.

Considered altogether, it would appear that the merits of tin roofs should claim more attention from house owners and architects than they receive at present.

USEFUL HINTS.

The finest kind of iron tubes ever used to convey gas, steam or water, were seamless drawn steel and brass tubes of almost any diameter and thickness.

HARD AND INATTACKABLE CEMENT.—"Kosmos" gives the following formula for the composition of a cement which sets in four or five days, when it becomes so hard as to scratch iron, serving to cover terraces, line fountain basins, and connect blocks of stone. Grind to a fine powder ninety-three parts of crushed brick or well-burnt clay with seven parts of litharge, and mix the powder with sufficient linseed oil to give the consistence of mortar. Before applying the cement, the parts to be covered must be damped with a wet sponge, and if any cracks should show themselves, they must be stopped up with cement.

PRESERVATION OF TIMBER FROM DAMP.—The following preparation is recommended by the *Genie Civil* for preserving timber from the ill effects and deterioration due to damp, while at the same time giving it a clean and pleasing appearance: Sulphur 500 parts, resin 375 parts, and fish oil seventy-five parts are melted together; and, when they are completely dissolved, a small quantity of red or yellow ochre or iron oxide, ground in linseed oil, is added for colouring, the whole being stirred vigorously to ensure a thorough mixture. Two coats of this paint in a boiling state are laid on, the first being allowed to dry thoroughly before the second is applied. It is said that timber thus treated will resist steam and fog as well as damp

HOW TO DRILL GLASS.—A writer in the *Scientific American* describes how to drill a hole in glass: Take a small common three-cornered saw file and break off an inch of the end of it. Then take to a grin stone and grind a blunt point on it, being careful not to hurt the temper. Leave the file in the handle and bore just like you would with an awl. The point of the file should not be longer than the file is thick. Use turpentine as a lubricant, and keep the cutting edges on points of the file sharp with an oil stone. I have bored holes two inches deep in a short time by hand in glass by this method. In boring a plate, I have found it best to bore from both sides, using very light pressure toward the last, always laying the plate solid on a paper bound book.

THE HOLDING POWER OF NAILS.—Relating to tests as to the relative holding power of cut and wire nails, we have, says the *Iron Age*, the following communication from a correspondent in India, who alludes to the effect of time on the holding power of wire nails: "In regard to the tests to be made as to the holding power of cut and wire nails, I wish to say that to make the tests of any value or significance, the work after being nailed should be allowed to stand for a week or two and the nail then drawn. It has been my experience that cases nailed with cut nails are easier to open with a nail puller than the same cases in which steel nails have been used. The cut nail after starting comes out easy, whereas the wire nail holds its full length. Carpenters also say that in taking off shingle roofs that have been nailed with wire nails the shingles break and the nails all remain in the sheeting.

DISPOSITION OF CONCRETE.—When concrete is used to obviate the yieldingness of the soil to pressure, expanse or extent of base is required to answer the end, and to secure this effect, says the *Builder's Reporter*, the concrete being widely spread, should be thick or deep only with reference to its own power of transmitting to the ground the weight of the wall to be built upon it, without breaking across or being crushed. But when concrete is used as a substitute for a wall in carrying a wall down to a low level, it is in fact a wall, wide only in proportion to its comparative weakness in the absence of manipulated bond in its construction, and incased by the strong soil within which it is placed. Whether the proper object be the attainment of a sufficiently expanded base upon a weak soil, or of the sufficient depth below ground in a strong soil, it may be, to exclude meteoric influences, the erroneous notion is that a foundation is rendered strong in the use of concrete by depth rather than by extent of base, and in consequence of this notion heavy buildings are sometimes jeopardized by the friable concrete foundation being placed on its edge instead of being laid flat to cover the breadth of soil necessary to withstand the weight of the superstructure. Concrete, indeed, is at all times more safely to be regarded as a substance to be placed as a layer than as a substance to be set up as a wall, for although with good materials, careful manipulation and patience, excellent erections as walls may be made of concrete, as erections in the same form may be made of tempered clay, neither concrete nor tempered clay is to be regarded as a proper substance with which to form the lofty walls of buildings in towns.

Messrs. P. G. Waters & Son of Hull, Que., have just completed the construction, for the Public Works Department at Ottawa, of what is said to be the largest lifting dredge in America. Its total length is 152 feet; width, 30½ feet; height, 14 feet, the well being 91 feet 9 inches long and 6 feet wide. The machine is capable of dredging to a depth of 50 feet. It will cost in the neighboorhood of $70,000.

VOL. VI.—No. IX. SEPTEMBER, 1893 { PRICE 20 CENTS / $2.00 PER YEAR.

—THE—
CANADIAN ARCHITECT AND BUILDER,
A Monthly Journal of Modern Constructive Methods.
(With a Weekly Intermediate Edition—The CANADIAN CONTRACT RECORD),
PUBLISHED ON THE THIRD THURSDAY IN EACH MONTH IN THE INTEREST OF
ARCHITECTS, CIVIL AND SANITARY ENGINEERS, PLUMBERS, DECORATORS, BUILDERS, CONTRACTORS, AND MANUFACTURERS OF AND DEALERS IN BUILDING MATERIALS AND APPLIANCES.

C. H. MORTIMER, Publisher,
Confederation Life Building, - TORONTO, CANADA.
Telephone 2362.
64 TEMPLE BUILDING, - MONTREAL.
Bell Telephone 2299.

SUBSCRIPTIONS.
The CANADIAN ARCHITECT AND BUILDER will be mailed to any address in Canada or the United States for $2.00 per year. The price to subscribers in foreign countries, is $2.50. Subscriptions are payable in advance. The paper will be discontinued at expiration of term paid for, if so stipulated by the subscriber; but where no such understanding exists, will be continued until instructions to discontinue are received and all arrearages paid.

ADVERTISEMENTS.
Prices for advertising sent promptly on application. Orders for advertising should reach the office of publication not later than the 12th day of the month, and changes of advertisements not later than the 5th day of the month.

EDITOR'S ANNOUNCEMENTS.
Contributions of technical value to the persons in whose interests this journal is published, are cordially invited. Subscribers are also requested to forward newspaper clippings or written items of interest from their respective localities.

The "Canadian Architect and Builder" is the official paper of the Architectural Associations of Ontario and Quebec.

The publisher desires to ensure the regular and prompt delivery of this Journal to every subscriber, and requests that any cause of complaint in this particular be reported at once to the office of publication. Subscribers who may change their address should also give prompt notice of same, and in doing so, should give both the old and new address.

THE by-law under which $155,000 was expended in the erection of new County buildings at Woodstock, Ont., has been declared informal, a vote of the ratepayers not having been taken upon it as required by law. A special meeting of the County Council has been called to frame a new by-law.

THE young architect should be taught to regard the ability to climb a ladder or a series of ladders as one of the essential qualifications of his profession. Without this ability he is not in a position to see for himself that the work on the parts of his building which can be reached only by scaling a ladder, is being properly carried out. Some architects are lacking in this requirement, and rather than take the chances of a fall, are content to take for granted the quality of the work at the top of the ladders.

THE passenger elevator, which has come to be such a universal and highly appreciated feature of every important office building in America, is but little known in Europe. The disappointment in this respect of the Canadian who visits England and is continually obliged to climb stairs is in inverse ratio to that of the European visitor to Canada, who is delighted to find himself carried from bottom to top of the highest buildings without exertion and within the period of a few seconds.

AMERICAN architects are sharing the burden of the depression which at present exists throughout the United States. In New York, Chicago and other large American cities, the staffs are being greatly reduced in architectural offices. Some Canadian draughtsmen employed in American cities have been so fortunate as to be retained in their situations, whilst others have been deprived of them, and are finding their way back to the Dominion where, unfortunately, the chances for employment are none too frequent.

ANOTHER derrick broke down while under strain in Toronto the other day, one of the chains striking and seriously injuring an attendant. The frequency with which accidents of this character have recently occurred should lead contractors to be more careful to see that derricks are sufficiently strong for the work which they are required to perform. If greater care is not exercised the Legislature should step in and protect the lives of workmen. Not alone in Canada but in Great Britain and Australia, accidents from this cause have become frequent, and the necessity of enforcing greater carefulness in order that they may be avoided is properly engaging attention.

A COMPANY has been formed with the object of erecting a crematory in the City of Toronto. The cost of the building and equipment are placed at about $3,000. A description of the design of the proposed building and of the process of incineration of human bodies, has appeared in the daily press. The amount which is proposed to be risked on the experiment is small, and it is perhaps well for the investors that it is so. The outlook for the success of the venture does not appear to us to be very encouraging. We were recently afforded some particulars concerning the crematory at Buffalo which go to show that the institution has not been a profitable one, the favor bestowed on the new method having been of a very disappointing character. If such has been the result in an American city, there is less reason to expect that so important a deprature from established usage will meet with approval in a community where the people are known to be more conservative in their views.

WITH the close of the vacation and the approach of the long evenings incident to autumn and winter, the present would seem to be a fitting time to consider the proposal which has been made that an Architectural Club, composed of architects and students, should if possible be established in Toronto. The desirability of forming a local organization which would provide means of social relaqation as well as profitable instruction for the architects and students of the city, and which would receive the united support of these classes, was clearly set forth in the letter by Mr. A. H. Gregg announcing the dissolution of the Toronto Architectural Club at the close of last winter. We hope that Mr. Gregg will further endeavor to enlist the co-operation of those who should be interested in an endeavor to give practical shape to the idea.

RECENT legislation and the increased caution exercised by the loan companies is strongly tending to force out of the ranks of the builders those who possess little or no capital. These causes, aside from the lifeless condition of the real estate market, are operating to check speculative building in Toronto. Under present conditions the loan companies will not advance money to the builder until his building is ready to be roofed in, and not then even unless he can present a statutory declaration in accordance with the provisions of the amended Mechanics' Lien Law, showing that not more than fourteen days wages are due to his employees. Should the mortgagor fail to satisfy himself on this point before granting a loan, the claim of the employees for arrears of wages is given priority over the mortgage. Under clause 6 of the amended Mechanics' Lien Act, a similar declaration is required for the protection of the owner before payments are made to the builder on account of the work done on his contract. All this means that the builder must have the means to purchase considerable material and pay the wages of his workmen until his contract is well advanced.

WE are pleased to observe that the remarks recently printed in this journal anent the improvement of the water front of the City of Toronto, are seconded in an editorial which has appeared in the Toronto *Globe*, the writer of which says: "On the waterfront is a great stretch of property, from Yonge to York street, affording admirable dockage for the steadily-increasing fleet of passenger steamers that make their head-quarters in Toronto. They carry hundreds of thousands of passengers yearly, many of them tourists, who spend large sums in Toronto. These visitors obtain their first impressions of Toronto, in many cases, from the temporary and ugly sheds around the wharves. First impressions last. The Mayor and Council should see to it that the present season ends all this. The land in question was, after a bitter fight with the C. P. R., reserved for public docks. Full possession of it will be secured in a few weeks at latest, and before the end of the year new and substantial wharves should be build, the place reserved for a public square fixed upon, and reclamation work begun. It will be too late to build the wharves next season before lake traffic opens. The work, if done now, will pay the city a large dividend and will do much to expand the already large lake travel."

THE untiring energy of Mr. E. A. Macdonald has once again revived the Georgian Bay canal scheme. With much adroitness he has presented a tempting prospectus—a ship canal and shortened navigation; a power canal with an unlimited supply of water capable of developing more electrical energy than Toronto can use for many a long year; and Lake Simcoe—a happy solution of the water question. The canal question, with shortened water route to the north west lakes, will always present attractions: there are many reasons why the question should be carefully debated; there is good reason for believing that shortened water routes will be acceptable to the commerce of the country. The present canal project alone, (independently of the water power and supply), is one of immense magnitude. To bring the level of Lake Huron to the south side of the water shed known as the Oak Ridges, will require cuttings from 150 to 180 feet deep. When Lesseps tried to do this on his Panama canal, he brought down the whole country side into his canal. In the construction of the Manchester ship canal in England, the route was much better known than the country between Toronto and Collingwood. It had been carefully surveyed and was thoroughly examined. There were ample data at hand to determine the topography and geology of the route; the promotors were in possession of the fullest possible information before the work was commenced. Unforseen difficulties encountered during the construction caused the ruin of the company, who had to appeal to the City of Manchester for a very large sum of money to help them along. The Georgian Bay canal and aqueduct scheme is in its present form a visionary proposal, projected by some unknown philanthropic American capitalists for the special benefit of "land poor" Toronto. It is one with which the City of Toronto should have no dealings till it comes recommended by the Board of Trade and some large financial institutions.

MR. SALEY, editor of the *Northwestern Lumberman*, presented a paper to the International Forestry Congress at Chicago, entitled, "Ignorance Concerning Woods." It may interest architects to read his opinion as to their knowledge of the qualities of the various kinds of wood employed in building. It is contained in the following extract: "If I were to arraign more severely one class of men than another for their ignorance concerning woods, it would be our architects, for the reason that it is their business to know. They can tell us about the wearing quality of different stones, the crushing strength of this material and that, but when it comes to any specific knowledge of the lumber used inside of our houses for doors, casings, floors, mopboards and possibly ceilings—objects which are constantly before our eyes—they are wofully ignorant. When furnishing a fine house you select for one room furniture, carpets and draperies of colors to blend, and for adjoining rooms other shades to carry out a general idea of harmony. If the upholstering of the furniture, the carpets, or the portières were to turn another color the harmony would be destroyed. So it may be destroyed through lack of knowledge on the part of the architect. Were you to ask the question, 'I desire to finish my front parlor in one kind of wood, my back parlor in another, the reception-hall in another, my library in another; now as these rooms are practically one, what woods shall I use in order that the harmony may be preserved after the house shall have been in use for years?' I am fearful you would fail to find an architect who could answer it. Architects pay little attention to these vital points, which are really most intimately connected with their business—in fact, are and should be regarded as a part of their business. I am not aware that an architectural journal has given a line to this subject, and the furniture papers are equally dumb." The above criticism could not be fairly applied to Canadian architects, the majority of whom have at least a fairly satisfactory acquaintance with the different varieties of wood. That this acquaintance might with advantage be improved is, however, not to be disputed, and it is also a fact that in no other country can the knowledge be more easily acquired. In this connection we would express the hope that the valuable series of tests of native building stones conducted last year at the School of Practical Science, Toronto, under the direction of a committee appointed by the O. A. A., will in the near future be supplemented by a series of tests under similar conditions, of native woods.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.

The annual meeting of the above Association will be held in the Legislative buildings, city of Quebec, on Thursday, the 28th inst. There will be held both forenoon and afternoon sessions: one of the principal subjects for discussion will probably be the tariff of charges which the Association has asked the legislature to authorize. It is expected that papers will be read by Quebec and Montreal members of the Association. In the evening the annual Association dinner will be held at the Florence Hotel, invitations to which have been extended to members of the Quebec Government, the Rector of Laval University, the Mayor of Quebec, officers of the Ontario Association of Architects, and representatives of the press.

Mr. Thos. Beatty, a respected member of the Toronto Builders' Exchange, died at his residence in Toronto a fortnight ago. The members of the Exchange in a body attended the funeral.

CORRESPONDENCE.

[Letters are invited for this department on subjects related to the building interests. To secure insertion, all communications must be accompanied by the name and address of the author, not necessarily for publication. The publisher will not assume responsibility for the opinions of correspondents.]

ENGLISH STAINED GLASS FOR CANADA.

Three very large and handsome windows of stained glass have just been completed by a local firm (Messrs. Wails & Strang of Westgate-road) and forwarded for shipment to Halifax, Nova Scotia. They are designed for St. Paul's, Halifax, the oldest, largest and most wealthy church in Nova Scotia and commemorate the late Judge of Equity of the Province, John W. Ritchie one of whose brothers is a judge of the Supreme Court of Nova Scotia, and another Sir William Ritchie, recently deceased, was Chief Justice of Canada. These windows are to be erected in the east end of the chancel of the church, and from very superior examples of the glass stainer's art. The subjects are drawn from the life of the Saviour, the central window representing the Ascension, and those to the right and left the bearing of the cross and resurrection respectively. It is interesting to know that this particular industry of Newcastle is largely represented in Canada, the firm in question having numerous examples of their art in Nova Scotia, New Brunswick, Toronto, and throughout the Dominion generally.—*The Newcastle Chronicle.*

Editor CANADIAN ARCHITECT AND BUILDER.

DEAR SIR,—The enclosed clipping from an Englsh newspaper has come under our notice, and we think merits attention. While every one with true artistic instincts would welcome undoubted specimens of the work of the best English designers in stained glass, it seems a cause for regret that when commissions of this kind represents a moderate outlay of money, it should not be spent in Canada. Work such as the firm in question does can be and is easily surpassed by Canadian firms. It is surely time that the idea, so prevalent formerly in other lines, that an imported article is necessarily superior, should have been exploded also in this branch of work as it has in many others.

Yours truly,

ELLIOTT & SON,
94 Bay Street, Toronto.

OBJECT LESSONS FOR STUDENTS.

TORONTO, Sept. 12, 1893.

Editor CANADIAN ARCHITECT AND BUILDER.

SIR,—I beg to submit herewith a few observations and queries touching work in course of erection as a means of education to students of architecture.

Competent builders must be, first of all, practical men. The practical side of the work does not enter so largely into the essential qualifications of an architect, but the more practical architects and draughtsmen are, the more pleasant will be the relations of all branches of the "allied arts," and the more satisfactory will be the results of all their efforts.

In obtaining the practical knowledge so much to be desired, all students of architecture will no doubt regard works in course of erection as the most helpful. But to what extent do students avail themselves of this help, and to what extent is it available in proportion to the great benefits which should be derived therefrom? An individual draughtsman with ambition, energy, perception and common sense, will occasionally betake himself to some particular job for the purpose of gathering some bits of information. So, also, an opportunity is sometimes afforded to students or architects to visit a special work in a body, under the guidance of an experienced head, thus making such a visit of great interest and profit. But the writer believes that such visits as those referred to constitute a very small part of the attention which should be given to works in course of erection; and I desire to mention one circumstance which I believe operates more than any other to discourage and limit the use of this kind of study. This restraining influence is the fact that all works of such a nature as to be interesting to the student are hedged about more or less with notices of "No Admittance," etc., and a general air of exclusiveness which is not at all conducive to quiet and peaceful observation. I know it is necessary to keep the general public outside of certain limits, to carry on work. Should one venture to penetrate a little beyond this limit, he is very likely to be made to understand that he is regarded as an intruder, and an interference with the progress of the work.

Generally, by going to more of less trouble, a student can get permission to make a solitary visit, or possibly more, to an attractive work. But would it not encourage students to seek out these attractions more frequently if the privileges sought were to be expected as a matter of common courtesy to the profession, instead of being obtained as a special favor?

There are at all times works going on in this city which would be of very great interest and value as objects of study could one but feel at liberty to spend a few minutes on them now and again while passing and repassing, as they are progressing. The City Hall and Court House and the new Drill Shed might be cited as splendid examples of first-class work. Of particular interest to some students would the iron roof trusses of the Drill Shed be in their present stage. Will anybody pretend that these and other works are benefitting as they should the students of architecture of the city?

Suppose it should be announced throughout the province that Toronto proposed to expend two millions of dollars or so in the next five years in providing the best possible object lessons for students of architecture, would it not create great enthusiasm? And is not just such work being done without any regard for its utility in the direction here suggested?

Now I believe, that if it was generally understood throughout the building trades, and among architects and students, that a special uniform card or badge, presented at the entrance to any work, public or private, would secure cheerful admittance and courteous treatment within reasonable limitations, students would make ten such visits for every one that is now made. Would not such an arrangement be worthy of the kindly consideration of architects and builders, with a view of placing practical knowledge within easier reach of those interested, in some such way as here suggested?

STUDENT.

ILLUSTRATIONS.

DESIGN FOR A SMALL TOWN HOUSE.

The house comprises parlor, dining room and kitchen on ground floor, four bed rooms and bath room on first floor, and two bed rooms and store room in attic, besides closets, pantries, &c. It is of frame construction. Externally the entire building may be shingled, or if desired, clap boards may be used up to the water-table above ground floor.

If cedar shingles be used, they will need no staining, but the window sash and frame and all other external woodwork should be painted white. Interior wood work, if of pine, should be painted white or in light tones to harmonize with the decorations of the various rooms.

A sheet of details to accompany this design will be published in the ARCHITECT AND BUILDER for October.

This house would cost, according to local conditions, from $2,000 to $2,500.

HOUSE ON ST. GEORGE STREET, TORONTO, FOR MR. ALEX. MCARTHUR.—D. B. DICK, ARCHITECT.

In this house all the cut stone work, also the coursing and squared rubble, are of brown Credit Valley stone, and the gables are tile hung. The house contains 4 public rooms and 9 bedrooms and dressing rooms, exclusive of those for servants; also 2 bathrooms. The principal rooms, the bathrooms and the main halls and staircase, are all finished in polished hardwoods of different kinds, including quarter cut white oak, mahogany, bird's eye maple, cherry and chestnut. The windows are finished with sliding shutters. The house and conservatory are warmed by hot water, and the lighting throughout is by gas and electric light combination fixtures. The total cost was about $25,000.

CARVED PANELS IN THE RESIDENCE OF MR. DUNCAN MCINTYRE, MONTREAL.—W. T. THOMAS, ARCHITECT; H. BEAUMONT, SCULPTOR.

ERSKINE CHURCH, MONTREAL.—A. C. HUTCHISON, ARCHITECT.

PERSONAL.

Mr. A. E. Wells, who during the last year has been in the office of a New York architectural firm, spent his vacation in Toronto and at Niagara-on-the-Lake.

The marriage is announced at St. Southsea, Eng., on the 3rd of August, of Mr. E. W. Rathbun, president of the Rathbun Co., Deseronto, Ont., to Miss Aileen Blair.

Mr. Richard Bond, who was one of the pioneers in railroad construction in Canada, died at his daughter's residence in Toronto on the 12th of August, aged 82 years.

TO MAKE POSITIVE COPIES OF DRAWINGS.—The paper to receive the impression is coated with a two per cent. solution of bichromate of ammonium, to which a little grape sugar has been added and then dried in the dark. The sheet containing the drawing is laid upon the prepared paper and exposed to the light until the paper has assumed a gray color. It is now dipped into a 1 per cent solution of nitrate of silver, one-tenth of the volume of which consists of acetic acid. The positive image developed thereby becomes dark brown on drying.

QUESTIONS AND ANSWERS.

[Readers are invited to ask through this department for any information which they may require on lines consistent with the objects of the paper. Every effort will be made to furnish satisfactory answers to all such inquiries. Readers are requested to supply information which would assist us in our replies. The names and addresses of correspondents must accompany their communications, but not necessarily for publication.]

A Nova Scotia subscriber, "H. E. G.," writes: Can you give me the name of the Professor in Architecture in the School of Practical Science, Toronto. I desire to apply for particulars regarding tuition, etc.

Ans.—Address Mr. C. H. C. Wright, Lecturer in Architecture, School of Practical Science, Toronto.

THE DORIC ORDER.

IN the Doric order, the number of channels is either sixteen or twenty,—afterwards increased in the other orders to twenty-four; for they are invariably of an even number, capable of being divided by four; so that there shall always be a center flute on each side of the column, that is, in a line with the middle of each side of the abacus. Doric flutings are much broader and shallower than those of the Ionic or Corinthian orders; broader for two reasons,—first because they are fewer in number; and secondly, because there are no *fillets* or plain spaces left between them on the surface of the shaft. Their proportionately much greater shallowness, again, may be accounted for equally well; were the channels deeper not only would they seem to cut into the shaft too much, and weaken it, but also produce much too strong shadows, and another inconvenience would be occasioned, for the *arrises* or ridges between the channels would become very sharp and thin, and liable to be injured. The mode of fluting Doric columns with more *arrises* between the channels instead of fillets, has been retained by the moderns as characteristic of the order; but, as the order has been treated by them, it is little better than a mere distinction, with very little regard to general character. In the original Doric, almost every part is marked by breadth or by flatness, or by sharpness. There are no curved mouldings or surfaces, except the *cymatium* of the cornice and the *echinus* of the capital, which last is generally kept exceedingly flat. The breadth and shallowness of the channels, and the flat curves in which they commence and terminate, are therefore in perfect keeping with the style in other respects; so also are the sharp arrises or ridges between the channels or flutings on the surface of the shaft, they being expressive of a severe simplicity. The same remark applies to the horizontal annular narrower channels or more incision immediately beneath the echinus of the capital, and lower down, which last are just the reverse of the projecting astragal or convex mouldings given to the Doric capital by the moderns. Why such horizontal channels or grooves should have been cut in the very thinnest and weakest part of the column, where they diminish instead of adding to strength, it is not easy to say, except that they were merely for the sake of effect,—of producing shadow, and increasing the proportions of the capital to which they belong. We leave others, should any be so disposed, to object that the lowermost groove or grooves, as the case may be, give the capital the appearance of being a separate piece, merely joined on to the shaft, without such joining being concealed. Looking at it differently, we will rather say that such groove is intended to mark to the eye the commencement of the capital, the proportion above it of the shaft being thereby converted into the *hypotrachelium* or necking of the capital itself, which is thus enlarged in appearance, without being actually increased, and rendered unduly heavy. It is not, however, every example of the order that has such necking; while in some the groove separating the capital from the shaft is diminished to a mere line,—which looks like a joining not intended to show itself,—in others it is omitted altogether. With respect to the echinus we have little more to remark than that its office—which it performs admirably,—is by expanding out, to connect the diminished upper end of the column with the overhanging abacus; and the former being circular and the latter square, but adapted to each other in size, a beautiful combination is produced of a circle inscribed within a square; and the result is variety, contrast, and harmony. In its profile or section—by which latter term is understood the contour of any moulding or other member,—it is usually very flat, little more than a portion of a cone (turned downwards), with scarcely any perceptible degree of convexity, except just beneath the abacus, where it is suddenly rounded and diminished, so that the abacus does not seem to press upon or compress it too much.—*Granite Cutter's Journal.*

MONTREAL.

(Correspondence of the CANADIAN ARCHITECT AND BUILDER.)

The Building Inspector for the city of Montreal is a most efficient officer, and might well be taken as an example by the inspectors in other Canadian cities. Scarcely a week passes in which he does not figure as the prosecutor of persons who violate the city building ordinance. He has just entered actions against a number of individuals and corporations for having neglected to take out permits for new buildings. I have noticed by the ARCHITECT AND BUILDER that the by-laws of Toronto Hamilton and other cities are not complied with in this respect, and that no determined effort on the part of the Inspectors appears to be made to enforce the law. Building laws, like laws of other kinds, are valueless if not enforced.

The contractors for public works have been complaining for some time past of the scarcity of workmen, and in some cases have sent into the country to endeavor to secure laborers. Notwithstanding this condition of affairs, the local unions have petitioned the Council against allowing the employment of outside workmen. Such a dog in the manger spirit deserves no encouragement.

A petition is being largely signed by the citizens for presentation to the City Council asking that the Chateau de Ramezay opposite the City Hall be purchased by the city and used as a public library and museum. The petition states that the Chateau is one of the few remaining buildings of the old regime, and by reason of its historic importance as a monument of old Ville Marie, should be preserved.

Several actions at law have arisen out of the construction of a large chimney for the Royal Electric Company. The design for the chimney was prepared by Mr. McLea Walbank, architect. Mr. Alex. Wand was the contractor for the work. Owing as it is alleged to defects having been discovered subsequent to completion, a portion of the chimney was torn down and rebuilt. For this purpose it is said the plans were modified. Mr. Wand brought an action for the value of his work, but the case was dismissed. Now the company has brought suit for the cost of demolition and reconstruction of the chimney on the new plans; and Mr. Wand is suing the architect, on the ground that the loss and damage were not caused through any fault of the workmanship, but through defective plans.

From the twenty-five designs submitted by artists for the statue to be erected on Dominion Square to the memory of the late Right Hon. Sir John A. Macdonald, the Design Committee acting with the advice of experts, have chosen that of Mr. Geo. E. Wade, the well known London sculptor. The statue will cost $20,000, and is to be ready to be unveiled during the autumn of 1894.

Messrs. Vanier & Keefer, the engineers appointed to report on the means which should be adopted to improve the efficiency of the Montreal city water works, has recommended the expenditure of $100,000 in new plant and improvements, including a 10,000,000 gallon pumping engine and a new engine for the high level service.

OTTAWA.

(Correspondence of the CANADIAN ARCHITECT AND BUILDER.)

The total expenditure on the erection of new buildings and on improvements to existing buildings in this city during the last year is stated at $350,000. This is about equal to the amount expended in 1892, and considerably less than in some previous years. In view of the scarcity of dwellings of moderate size and the high rentals which owing to this fact must be paid by those who are not fortunate enough to own their own houses, a good opportunity appears to exist for builders to make money by erecting a number of dwellings of the class mentioned. Enquiry reveals the fact that rents are very much higher in Ottawa than in Toronto.

While writing on this subject I may also refer to the excessive water rate which is imposed in this city. I was recently informed by a gentleman residing here, and who is the owner of property in Toronto, that the cost of water in Ottawa is more than double what it is in Toronto. It is difficult to understand why this should be the case, seeing that in this city there is no expensive pumping plant to be maintained, such as exists in Toronto. It would seem that large profits are being derived from the sale of water, and are applied to pay the expense of other departments of the public service. If so, the principle is a wrong one, and the citizens should insist on each department being maintained on a distinct footing.

Building operations at Stratford, Ont., during the present year are said to be 50 per cent. in excess of 1892.

TECHNICAL REQUIREMENTS OF ARCHITECTS.

WHAT to specify is a question that often gives rise to some hesitation in the minds of many architects. They can design with tolerable completeness in the main structure, its general accommodation, the plan of its floors; but when the fittings and details have to be considered, the extent of the architect's knowledge is reached. The rest is technical and precise; it is thought to have no connections with, or relation to the design. Many in the profession think that their proper and legitimate work is accomplished when they have prepared the design, and that they have nothing to do with questions of heating, lighting, or ventilation; what kind of appliances and fittings are to be provided and fixed. If we should ever come to view the art in this light, we should be ignoring completely all opportunities of making architecture commensurate with the progress of science and the development of our industries. This view of restricting the building art would be to keep architecture back, and to prevent her from controlling and moulding the agencies which affect our civilization and material wants. If art is really to direct the fashioning of our commonest objects, of our chairs and tables, and to permeate the everyday objects of our domestic life, it is the true office of architecture to bring everything that contributes to the convenience and comfort of our buildings under her influence. The radiator, the heating stove, the electrolier, the gasolier, the ventilating inlet and outlet, even those appliances by which we perform the commonest functions of life or of trade, fall rightly under its influence. If we think aright, what has been called the "hierarchy" of art implies a descending scale. The modes of classification adopted, such as that which makes Architecture, Sculpture, and Painting the primary trinity, have apparently excluded the useful arts. These three primary arts represent an ascendency of thought and feeling from the structure raised by the architect to the more idealised and ethereal productions of the sculptor and painter; the material yields to the spiritual. But does not architedture represent more than the mere outside shell of the building? Does it not descend to every fitting and contrivance which finds a place in the building? We have too long set a limit to architecture, and we have not considered that it commences at the very beginning of the conversion of the raw materials, and also includes everything besides floors and walls, doors and windows.

These thoughts are necessary to help us to see the universality of the art of the architect, that his work is wider and deeper than that of making an embellished building of brick or stone, and then leaving it to be finished and made convenient, or comfortable, or healthy by the fitter or engineer. Specification ought to imply selection. What to select is as important a question to the architect as how to design, because the exercise of his knowledge and taste may be, and is often, quite as much called into requisition by one as the other. For example, in looking over an illustrated catalogue, or the stock of goods in a showroom of an ironmonger, the architect has to call into exercise many of those very faculties he uses in designing the given article. If it is a drawing-room stove, he has to look to see whether the construction is likely to be economical in the use of fuel, whether the firebrick back is of good form for radiating the heat, and the opening for smoke shaped so as to avoid eddying currents and smokiness. He chooses the one which he thinks will be the best; he will avoid the more ornamental patterns, or those which are unnecessarily showy with cast ornament tiles and brasswork. But if the stove is merely specified in the usual terms, and the selection is left to the employer or to the builder—a mode often adopted—a very different result follows. Probably the most showy and the least efficient as a fuel economizer and heat radiator will be selected. To specify and not to select is an imperfect procedure, calculated to bring discredit on the architect, while it only gives temporary pleasure to the employer. In matters requiring scientific knowledge, the architect's opinion may be asked—say, for example, a heating apparatus, or a ventilating exhaust; but in artistic things, like ornamental gas-fittings or tesselated paving, the selection is often left to the client, who thinks himself quite as good a judge in matters of taste. The provisional sum inserted in specifications has at least the effect of preventing a contractor supplying inferior articles. An amount may be provided for a mantel piece or any decorative work, but unless the architect has a voice in the design, even this mode of provision may be rendered of little value. Most specifications are two discursive and inexplicit, and architects unfortunately attach little importance to inventions and appliances, imagining that it is not their principal business. The great evil of this indifference to fittings and details is that the makers cater to please the public taste, for if there is no one to select and examine that knows something about the matter, they have no encouragement to make valuable improvements, or to expend capital in the production of artistic designs.

Three principal classes of goods comes under the notice of the architect in specifying. The first are the structural requirements and materials, in which we may include inventions to prevent the rising of damp in walls, damp-proof courses, materials for building walls, floors of fireproof construction, window-sashes, iron work; a second class comprehends the various internal fittings of buildings, like sanitary, gas, electric-light fittings, heating and ventilating appliances; and the third class artistic and decorative details.

Certain principles of specification are necessary to be observed: (1) An architect must know what he wants, for if he does not, he is likely to be contented with anything that first offers itself to his mind. Many of those who write specifications depend on illustrated trade catalogues for their information; they select a certain article or pattern, and name it in the specification, because they have not made up their minds, or do not know exactly what they require. If, for example, an architect is carrying out baths and warehouses, he should know what kinds of private baths to specify—whether porcelain baths with glazed rims, whether cased, what hot and cold water fittings, what apparatus for shower or spray is to be fixed, what other necessary fittings—like electric bells, foot grid, wall lining, coat and hat pegs, and mirror—are to be provided. What he wants can only, therefore, be answered by a knowledge of the requirements of baths, and surely this it worth finding out before referring to a trade catalogue. In warming and ventilating it is absolutely necessary to find out the conditions of the building, how it is affected by cold winds, by cold surfaces such as glass, and to find out what proportion the heating surface must bear to the cubic feet of air necessary to be warmed. To specify without such knowledge is to leave all in the hands of the engineer or contractor, who may be tempted to take a very inadequate estimate of the requirements. (2) How to obtain it. The name of a firm is often a sufficient guarantee of skill and good workmanship. The architect may adequately supply his own deficiency by naming firms of repute to execute these works. The "approved apparatus" of the contract is often left to someone who has no reputation, and no one is responsible for its efficiency. But by naming any one of the firms which are known to do satisfactory work, the architect obtains at least competent experience and the guarantee of a responsible name. There are a few ways open to the architect. One of the best is to consult the pages of a respectable professional journal, where he may find lists of makers and vendors of building specialities. Our own Directory of the Building Trades may be of value. The larger firms whose special branches have a wide repute take care to draw attention to any improvements of manufacture or new appliances which they bring out, and the architect of to-day, if he desires to keep himself "up to date" with materials or improved systems, will find it necessary to make himself acquainted with them, or the catalogues and descriptive literature of well-known firms. Technicological museums are another means by which the profession and the tradesman can be brought to know each other's wants. An instance of a sanitary museum equipped with appliances for the instruction of builders we lately noticed instituted by the Hornsey Local Board. Attached to it is a library and testing room. The builders' "Exchange," so common in America, is a means of mutual benefit; and in connection with our technical schools and architectural schools, as that of King's College, a start has been made to collect typical specimens of manufactures and fittings, though very incomplete at present. The way of all others the most practical is to visit buildings and establishments where systems and goods have been produced, and to obtain experimental evidence of the actual working and effect. Firms of manufacturers often give the profession and Press opportunities of seeing for themselves the operation of improved appliances, though there is naturally a limit to this, as it is not always convenient to inspect public and private establishments in working order. These are some of the ways by which the practitioner may learn the value of specialities. In the artistic class he is more free, not being hampered by technical points and want of experience. What and how to specify is not the least onerous and responsible of the architect's duties, for it implies a wide knowledge of details, and a general acquaintance with the principles of science, more especially of hygiene, pneumatics, heat, and the laws of light and sound.—*Building News.*

DECORATION AND FURNITURE

LEADED WINDOWS.

THE increasing love of picturesqueness and quaintness in our dwellings has caused us to revive and admire in the present day many of the old customs and fashions of our remote forefathers. Strangely, too, says *Furniture and Decoration*, we have thus often reproduced from sheer choice those very things that were made some centuries ago from absolute necessity. In no matter

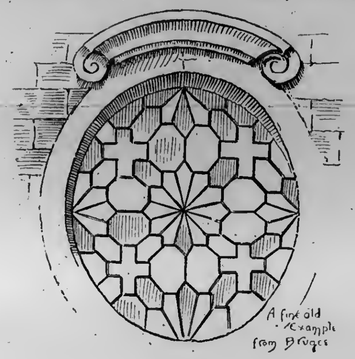

FIG. 1.

of household is this peculiar fact more demonstrated than in the present revival of leaded windows.

In olden days when glass was dear and difficult to make in large pieces the subtle cunning of "ye skilful glazier" prompted him to join his little bits of glass into a large window by means of grooved leads. Into these "cames" he set his small panes, adding piece to piece, until by dint of such conjunctions he produced a lattice or sliding window to fit the wall opening which it was his mission to fill.

Now these old leaded windows—even the simplest of them, as seen in some of the country cottages at the present time—are remarkably picturesque, and many of them are admirable lessons in design, and bespeak much gifted thought upon the part of him who first invented them. It is no wonder then that they are nowdays so assiduously studied and revived, and it is well that such charming and homely embellishments to the modern house should continue to be regarded with the admiration that they deserve.

The several fine old examples of leaded windows which appear on this page have been collected from various places at

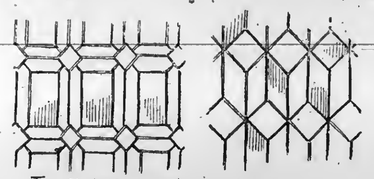

FIG. 2.

home and abroad, hence they are considerably diversified in character. The first sketch shows a delightful old window which we noted some time since in the sleepy silent town of Bruges. It is an example designed with consummate skill, and may be regarded as a standard of excellence in its particular style.

Figs. 2 and 3 are rough notes of two leaded windows existing at Moreton Hall, Cheshire. The first of these is simple and formal, but the second is more fanciful, and is evidently intended to illusively convey an idea of projection by the geometrical arrangements of the diamonds and straight bars.

The next example (Fig. 4) diverts our attention in the direction of French art, and will doubtless be useful to our conferes

FIG. 3.

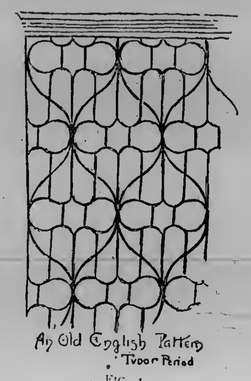

FIG. 4.

as a *bona fide* specimen of leaded work of the Louis Quinze period. It should not be forgotten that in much of the leaded work of that period, gilt was largely employed to enhance the effect.

The next sketch (Fig. 5) presents us with a beautiful specimen of old Tudor work. The flow of the lines and the consequent dropping of the pattern, the evident strength of the judiciously joined glass, are points that must at once commend this example to our attention. There is just sufficient Gothic feeling in it to make it interesting, whilst the abundance of easy curves in its outline make it agreeable even to the taste of those who dislike mediæval art.

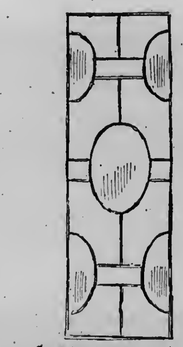

FIG. 5.

The last illustration is interesting, not only because of its design, but also on account of its associations. It is a sketch of a small window in Michael Angelo's private study in his house, or rather palace, at Florence. Whether it was designed by the great master or not it is impossible to say, but that it was in his house will be, to most of us, a sufficient recommendation of its beauty.

LEGAL DECISIONS.

MORRIS V. THARLE.—Judgment of the Chancery Court on appeal by the plaintiff from an order of Meredith, J., in Chambers, upon appeal from a Master's certificate, disallowing the claim of the plaintiff, a material man, to establish a mechanic's lien upon the land of the defendant Ryan, upon the ground that the registration was late, having regard to the times of the supplying of the materials. The court held that the plaintiff's sub-contract with the defendant Tharle, the contractor, must be considered a continuing contract for the supply of all the goods, and although some of the articles supplied were not within thirty days of the registration, the plaintiff was entitled to the benefit of his lien. Appeal allowed with costs, to be added to the plaintiff's claim.

SPANISH GLASS.—The first mention of glass works in Spain is found in Pliny and the next allusion to this is in the works of San Isadore, who lived in the seventh century. Glass was made to a great extent in the Spanish Peninsula during the Roman period. The manufacture had ceased to exist in the seventh century. There are no specimens of Spanish glass of the Visgothic period, but from the eighth to the fifteenth century it is inferred that the industry of glass making became as important in Spain as that of pottery. No specimens of the earlier period, however, have reached our time, and we must judge of what it is from the glass vessels belonging to the Renaissance period, which preserve their oriental form and are of a different style to that of Venice and other localities in Europe.

PAINTERS' MEASUREMENTS.

IN England the custom is to employ a clerk quick at figures, whose duty it is to take off, from the plans and specifications, an accurate list of all the materials and labor required in the performance of the work, setting down in each case the number of yards or feet, as the case may be, of each item. In the case of painting, the figures obtained for the carpenter and joiner prove of service also for the work to be done by the painter. The following is a table that is intended to indicate the method of measurement of painters' work, *and also the order in which the various items may be taken.* A similar table added to, or changed, as might be necessary to suit American methods of construction, would be very useful to have on hand when getting out estimates, as it would insure nothing being left out. The table which follows accurately indicates the English practice :

Lead, in oil on white work, at	——	per yard super.
" " cement "	"	" " "
Ornamental railings, etc.,	"	" " "
Skylights,	"	" " "
Skirtings, 12 in. girth and under, at	——	per ft. rm.

Brasses and simple items of a similar nature,	"	" "

A FAVORABLE COMPARISON.

MR. James A. Macdonald, architect, Regina, Assa., writes as follows : "Enclosed please find $2, for which please send to me for one year the CANADIAN ARCHITECT AND BUILDER. I have been taking your paper through the news dealers, and like it very much, as I consider it compares very favorably with the best American publications of the same class."

A FRENCH METHOD OF WARMING HOUSES.

To sum up these new methods, the teachings of M. Somesco, suggest that the natural porosity of the walls, especially the outer walls should not be destroyed. These walls should be decorated, not with paper and paint, but with porous, non-conducting substances, such as wooden drapery. The outer walls on the side nearest to the inner surface should be hollowed throughout, thus constituting a double wall, with a space of about four inches between the two walls. A heating contrivance, of whatever description may be found most expedient or economical, should be placed in the basement of the house. A warm-air chamber or shaft traveling round the base of the outer walls should supply to the hollow in the walls air taken from the outside and warmed at the point of admission in the wall to a temperature of from 100 degrees to 120 degrees Fahr. This should maintain the temperature of the inner wall at from 80 degrees to 90 degrees Fahr. Then he considers, the walls will radiate sufficient heat through the rooms to enable the inhabitants to constantly open the doors and windows, and to breathe cold, fresh, outer air without inconvenience. As a rule fires will be unnecessary, dampness will be completely banished from the house, and to maintain some moisture in the air it would, he thinks, be expedient to decorate the house with numerous evergreen plants. The inhabitants should then be able to benefit by unlimited ventilation, and could breathe pure, cold, and fresh air, coming upon them directly from the outside.—*Popular Science Monthly.*

USEFUL HINTS.

The following are the recipes of body and white glaze:—White body—74 lb. china clay; 18 lb. flint; 17¼ lb. stone; 3½ lb. plaster. All must be mixed together dry, before adding water, on account of the plaster. Dip the brick at 30 oz. to the pint slop, and pass the body twice through a fine sieve. White Glaze—19 lb. felspar; 6 lb. stone; 1½ lb. whiting; ¾ lb. flint; ½ lb. plaster; 2½ lb. best flint glass; 12 oz. white lead. Mix as above.

Conrad Mischler writes to the *Painters' Magazine*: "I have been painting iron work for the last 18 years and find that by using Venetian red, and brandon, thinned with raw linseed oil and japan, the article painted will stand the weather much better than when painted with any other. I painted two bridges some years ago which were not painted again until I did them after. One I painted with V. R. & B., as it is called, the other with red lead. The one painted with red lead was blistered and peeled to a great exient, while the other was in a very good condition. I painted them both over with V. R. & B., and they stand to-day looking almost as they did after being painted. Some ten years ago I painted the Fall River Railroad bridge with the V. R. & B. This bridge has iron beams in the water which I painted to low water mark, between tides. It has not been touched since, and has stood the wear of the water splendidly. I also painted an iron door with the same years ago, only giving it one coat. It is used every day by shop hands, and is clean and smooth to-day. I first clean the article thoroughly, and then use the V. R. & B. for the first coat, using for the next whatever color the party having the work done may desire. It has never failed to do everything expected of it, and has always given satisfaction. I have used red and white lead and experimented with all kinds of paint."

WEIGHT PER SQUARE FOOT OF SHEET IRON.—It will be interesting to those who have anything to do with sheet iron boiler plate or similar material to have an easily remembered rule for finding the weight per square foot of material they are working with. The *Ironmanger* says that it has been found by experience that a square foot of iron plate ⅛ inch thick weighed almost exactly five pounds, and this forms a basis for a very simple and easy rule. As a square foot of iron ⅛ inch thick weighs five pounds, a square foot of ¼ inch iron will weigh ten pounds, and we can say that the area of any sheet-iron (or plate iron) in square feet multiplied by the thickness in one-eighths and multiplied by five will give the weight of the piece. There is a piece of tank iron 5-16 inch thick, 3 feet wide and five feet long, how much does it weigh? The area will be 3 feet by 5 feet, or 15 square feet. Now how many eighths is 5-16 of an inch? Since ⅛=2-16 and 2 is contained in 5 2½ times, we say 5-16=2½ eighths, or 2½ times five pounds=12½ pounds per square foot, and as there are 16 square feet we have 15 by 12½ =1,875. Where the thickness is even eighths of an inch, it is much simpler; but even this is not a hard thing to do as shown. If it is desired to use this rule for other than iron, we simply find the difference between the weights of the two metals per cubic inch and find what a square foot ⅛ inch thick will weigh, then work as shown above.

ZINC IN ARCHITECTURE.—Copper plating sheet zinc for building purposes has recently been tried abroad with considerable success, the process being especially recommended where mechanical wear takes place. The zinc combines very well with the copper. The galvanic method of copper plating is advantageously used, but the zinc may also be coated with copper by ordinary means. In the first place the sheet zinc is cleaned with soda from any adhering dirt or grease, and is also purified by a weak acid bath from the covering of zinc oxide. There are then dissolved in twenty-four parts of water one part of refined verdigris and twelve parts of tartar, being heated to boiling point, after which three or four pints of Spanish white are added. The Spanish white is here decomposed and is precipitated as lime tartrate. The dark blue liquid is poured off and filtered, and can be used either as a bath for the sheet zinc or for the production of copper-plating paste. The first mode of action is the more recommendatory, as the fluid forces its way into the corners and angles of the zinc articles and is uniformly distributed all over. If it be desired to coat an immovable zinc object with copper, the article, after being cleaned, is painted with the copper solution and chalk compound, and, after drying, brushed. This very simple operation would likewise prove of value for architectural purposes where it is desired to remedy the generally unpleasing effect of zinc adornments.—*American Artizan.*

ENAMELLING SLATE BRICKS, &C.—Some five years ago, when first the manufacture of bricks and tiles from slate waste commenced to be made in North Wales, says the *British Clay Worker*, the white glazed brick was successfully produced by the following process and recipes:—The process is called the Biscuit-brick process—that is, the firing of the brick only slightly at first, all care being taken in setting and drawing the bricks so as not to damage them in any way. The bricks need to be fired at about half the customary heat for the first fire; they must then be taken to the dipping-house to be dipped in the body and glaze. Having everything in readiness, dip the part required to be glazed in clean water; you then pass on the brick to the next hand, whose dip will be the white body; then on to the next hand whose dip will also be the white body; again, pass on the brick to the fourth hand, whose dip will be to the glaze. Allow the brick to dry a little; then take a knife and scrape off all body and glaze that may have run over the side of the brick. The brick can then be set in the kiln to be fired again. The slate waste, however, is a ticklish material and will not stand a hard fire. The heat it will take is a good red clay heat; it will thus be seen that a down-draft kiln will not do for glazing slate waste. It must be fired in a kiln where all the flash heat can be kept from the brick—the kiln generally used is the Simmer muffle-kiln. The kiln itself when set with bricks is almost a box-kiln. The bricks must be fired gently at first, and when on full fire it must not be neglected or allowed to sink too low. The firing should be continued until the glaze has run bright.

MANUFACTURES AND MATERIALS

QUALITY OF SHINGLES.

TOUCHING on the shingle question in a paper on "Ignorance Concerning Woods," read at the International Forestry Congress, Chicago, Mr. Saley said: There are builders who really believe that the old-fashioned white pine shingle is out of the race. Cypress, red cedar and red wood are in fact supplanting it, but not for the reason that they are driving from the markets a poor roofing material. This shingle controversy is really amusing. Manufacturers tear from old roofs the kinds of shingles in which they are interested and hold them up to illustrate how durable they are. The fact is that a shingle of any of the woods named, or even of a meaner wood, would keep our heads dry as long as it will be necessary to protect them from dampness. To make shingles last still longer, lower, as some would say, the grade of them. That may sound paradoxical, and I am not aware that the theory holds in any other line. "A good thick shingle" is a term often heard. My preference would be to cover a building with a good thin shingle. A shingle, as a rule, wears out instead of rotting out, and the thinner the butt over which the water runs and drops on the shingle below, the longer the shingle underneath will last. A steady dropping, it is said, will wear away a stone, and the shorter distance the water falls the longer the stone will last. This philosophy applies with great exactness to the durability of shingles.

THE Stanstead Granite Company has been incorporated.

A charter of incorporation has been granted to the Wright Cement Co., of Hull, Que.

The Danville Slate Co., of Danville, Que., will it is said seek a market among the school-slate manufacturers in Germany.

The Rathbun Co. of Deseronto, lately purchased from Mr. E. B. Eddy, of Hull, machinery for the manufacture of patent lath and sheating.

A train comprising fifteen cars loaded with British Columbia shingles was recently despatched from Vancouver over the C. P. R. to Eastern Canada.

Steps are being taken at Quebec to organize a company with a capital of $100,000 to manufacture at St. Francois, pulp boards for interiors of buildings and furniture.

The Canadian exhibit of brick-making machinery at the World's Fair has attracted great attention and is constantly examined by United States and foreign experts.

A representative of the National Wall Paper Association of the United States, recently interviewed the Customs Department at Ottawa regarding the import tariff on wall paper.

The St. Johns Stone Chinaware Co., whose works at St. Johns, Que., were destroyed by fire some months ago, express their intention of rebuilding on the same site provided the town will grant them a bonus of $25,000.

The Rosedale Pressed Brick and Terra Cotta Co. has lately been organized in Toronto. The Company have leased a deposit of clay 27 acres in extent on the banks of the Don, and have erected buildings thereon. The necessary plant has been ordered, and manufacturing will shortly be commenced. Mr. John Flett is President of the Company, and Mr. J. V. Wright, Managing Director.

Artificially stained bricks of a rich chocolate color, and others made from clay mixed with soot, have been sometimes sold as black for ornamenting walls with diapers, checquers and strings. The latter description are very inferior, while surface-washed imitations weather indifferently. The *British Clay Worker* states that a little manganese and much iron in clay raised to an intense heat will produce bricks of no fleeting blackness.

Messrs. McRae & Co., of Ottawa, have secured control for Canada, of a German patent for seasoning and staining beech and birch woods. By the new process the sap is sweated out of the boards by being placed, in a green state, in steam chambers for twelve days, and subsequently for three days in a drying chamber. The wood is then by a chemical application stained a rich walnut color. Beech and birch thus treated have met with a favorable reception in the European market, to which part of the product of the Canadian kilns will be exported.

CANADIAN ARCHITECT AND BUILDER.

VOL. VI.—NO. X. OCTOBER, 1893 PRICE 20 CENTS $2.00 PER YEAR.

—THE—
CANADIAN ARCHITECT AND BUILDER,
A Monthly Journal of Modern Constructive Methods.
(With a Weekly Intermediate Edition—The CANADIAN CONTRACT RECORD),
PUBLISHED ON THE THIRD THURSDAY IN EACH MONTH IN THE INTEREST OF
ARCHITECTS, CIVIL AND SANITARY ENGINEERS, PLUMBERS, DECORATORS, BUILDERS, CONTRACTORS, AND MANUFACTURERS OF AND DEALERS IN BUILDING MATERIALS AND APPLIANCES.
C. H. MORTIMER, Publisher,
Confederation Life Building, - TORONTO, CANADA.
Telephone 2362.
64 TEMPLE BUILDING, - MONTREAL.
Bell Telephone 2299.

SUBSCRIPTIONS.

The CANADIAN ARCHITECT AND BUILDER will be mailed to any address in Canada or the United States for $2.00 per year. The price to subscribers in foreign countries, is $2.50. Subscriptions are payable in advance. The paper will be discontinued at expiration of term paid for, if so stipulated by the subscriber; but where no such understanding exists, will be continued until instructions to discontinue are received and all arrearages paid.

ADVERTISEMENTS.

Prices for advertising sent promptly on application. Orders for advertising should reach the office of publication not later than the 12th day of the month, and changes of advertisements not later than the 5th day of the month.

EDITOR'S ANNOUNCEMENTS.

Contributions of technical value to the persons in whose interests this journal is published, are cordially invited. Subscribers are also requested to forward newspaper clippings or written items of interest from their respective localities.

The "Canadian Architect and Builder" is the official paper of the Architectural Associations of Ontario and Quebec.

Subscribers who may change their address should give prompt notice of same. In doing so, give both old and new address. Notify the publisher of any irregularity in delivery of paper.

ONTARIO ASSOCIATION OF ARCHITECTS.

OFFICERS FOR 1893.

PRESIDENT	D. B. DICK, Toronto.
1ST VICE-PRESIDENT	KING ARNOLDI, Ottawa.
2ND VICE-PRESIDENT	JOHN E. BELCHER, Peterboro'.
TREASURER	EDMUND BURKE, Toronto.

COUNCIL:

DAVID EWART	Ottawa.

JOHN BARNARD, Treasurer.	JOHN LOGAN.
WM. J. HILL.	WM. PARK.
JOHN ALDRIDGE.	H. MARTIN.
JAS. CRANG.	

JOHN L. PHILLIPS, Secretary.

A CENSUS Bulletin recently issued by the Dominion Government shows that the workers in wood in the Dominion number 78,604; in stone, 30,856; in wood and stone combined, 10,201; and in metals, 49,476. The number of carpenters and joiners is 45,760; stone masons, 10,312; and painters and glaziers, 10,202.

THE evening classes in connection with the Toronto Technical School were resumed a fortnight ago. The attendance on the opening night was very large, and advantage is being taken to so great an extent of the instruction offered that the need of more commodious quarters is one with which the management will be confronted at an early date. The success which has attended the founding of this school is most gratifying to the advocates of technical instruction for the artisan classes.

THE annual report of the Ontario Bureau of Mines shows that there was produced in this province during the last year, common brick to the value of $980,000; plain pressed brick, $198,350; fancy pressed brick, $32,253; drain tile, $100,000. The value of stone quarried reaches $880,000. Cement to the value of $86,000 was placed on the market. The production of lime is valued at $350,000. Of a total mineral production of $5,374,000, $2,526,603 consisted of materials for use in architectural and engineering works.

IN view of the great scarcity of black walnut, once so plentiful in Canada, Mr. Joly has proposed to the farmers of Quebec that they should cultivate the walnut tree, as has been done in some of the Western States. The nuts after being left out all winter in heaps, covered with earth and straw, are in the spring planted two inches below the surface of the ground. The walnut tree is said to have a rapid growth. Mr. Joly's suggestion seems to be a valuable one, and we hope will receive the attention of the Forestry Department of the Government.

A French blacksmith named Ferdinand Allard, residing at Levis, Que., is said to have discovered a process of tempering copper. A small cannon tempered by his process is said to have been loaded to the muzzle with the most powerful powder driven in with a sledge and exploded without causing the least expansion of the barrel. A plate of copper three-eighths of an inch thick showed only slight indentation from the impact of rifle bullets fixed at forty yards distance with a force of two thousand pounds, while a hardened steel plate two inches thick was shattered to pieces from the same cause. The inventor of the process is confident that the most powerful projectile could not penetrate a ship the sides of which were protected with a 14-inch plate of copper which had been thus tempered.

IF we may judge by the published reports, the city of Winnipeg has become rid of the incubus imposed on her progress by the wild-cat speculation which a few years ago ran riot in that city. To all appearances the city has entered on a period of rapid and healthy development. The volume of building operations during the present year is stated to be about $1,884,450. This is as nearly as possible double in extent those of 1892, the aggregate of which was $900,000. The buildings erected this year consist largely of residences, for occupation by the owners. There is said to be a steady demand also for houses for renting purposes. The character of the residences built this year is said to be greatly superior to that of buildings of the same class formerly erected. There is said to be much demand for a better class of buildings for business purposes, and to meet

this the erection of a number of business blocks is in contemplation. It is anticipated that the coming year will witness even greater activity in building than that which has marked the present one.

THE new Board of Trade building in Montreal was formally opened a fortnight ago by our newly arrived Governor General, Lord Aberdeen. The occasion was marked by a banquet at the Windsor. Among the invited guests were many prominent lights in the commercial and political world. There was a great deal of speech-making. Properly enough much was said regarding the commercial interests of Montreal and the Dominion, and in praise of the part taken by the Montreal Board of Trade in the promotion of those interests. Singular, however, appears the fact that little or nothing was said about the new building itself, the completion of which was presumably the object of the gathering. Nor does a word appear in the report of the proceedings in commendation of the architect who designed and superintended the erection of the structure. There is nothing in the published report of the proceedings to show that he was even invited to take any part whatever in the opening ceremonies. We are at a loss to conclude whether the building is deemed unworthy of praise, or whether on payment of the architects fees, all the credit of the undertaking is supposed to revert to the financiers.

THE citizens of Toronto have been looking long and anxiously for indications of a return of the prosperity and steady progress experienced prior to the real estate boom, and the time of depression which followed in its wake. Architects and builders have naturally been amongst those who have watched most closely the situation, and will have reason to feel dissatisfied with the report of the assessors that the population has decreased during the year, and consequently that there are more vacant houses. Several errors have already been found in the report, and so little dependence is placed on its correctness, that a special police census has been ordered to be taken on the 1st of November to determine the actual condition of affairs. The opinion among architects and builders with whom we have discussed the subject appears to be that many of the houses which were vacant a year ago are now tenanted, and in consequence a moderate amount of building for residence purposes may be anticipated during the coming year. It is to be hoped that the result of the census will show this view to be the correct one. In any event, it can be said that the number of architects in Toronto is considerably greater than the present or prospective demand for their services would warrant, but in view of the commercial and industrial stagnation prevailing in the United States and other countries, there would seem to be great difficulty in the way of their removal to a more promising field.

THE City Engineer of Toronto was recently requested by resolution of the Council to report on the advisability of using native cement for concrete and other works. In his report he says: "Native Portland cement has been used on the works during the past year with very satisfactory results. Frequent tests are being made of this cement, and it is found to be of excellent quality, so that there is no objection to its use on city works, and it is not excluded therefrom. Regarding native natural cements, in my experience they are very much inferior to Portland cement. There may be, however, no special reason why they could not be used in some cases. For roadway work their use would involve considerable delay on account of their slow-setting character. The difference in cost between this cement and Portland cement, when used in concrete, would not be so great as is generally supposed, as a larger quantity of cement is required to be used to make a cubic yard of concrete. I have, however, inserted a clause in the specification for work which is now being advertised, providing that the contractor state in his form of tender the amount he is prepared to deduct from his contract price in case natural cement is ordered." In addition to the manufacture of natural cement which has been carried on extensively in Canada for many years, several companies have lately commenced the manufacture of Portland cement, as a result of which importations of cement are reported to have materially decreased.

A REPORT of the proceedings of the annual convention of the Province of Quebec Association of Architects appears in the in the present issue. Owing probably to the fact of the meeting being held in Quebec, the attendance was small, and the business transacted principally of a routine character. A couple of excellent papers were presented by Messrs. A. T. Taylor and Chas. Baillairgé. We regard it as unfortunate that the visits to points of interest precluded discussion of them. It is gratifying to notice that the importance of proper facilities being provided for the study of architecture has impressed the minds of leading men in the profession in the Province of Quebec. It is to be hoped that the attention bestowed on the subject at this convention will serve to call public notice thereto, and assist in paving the way for the establishment of a Chair of Architecture in connection with one of the great local universities. We regard this as by far the most important work to which the efforts of the Association can be directed. Had Mr. Baillairgé in his otherwise admirable paper kept more closely to this subject, he might have laid before the public a much stronger case on behalf of the proper training of those who will be the architects of the future, and we hope that at some future time he will return to the subject and for the benefit of the profession and the public review it in all its aspects. Mr. Taylor's paper on the Architecture of the World's Fair is a most skilful and interesting portrayal of his observations at the "White City." It is interesting to compare the facts as stated in this paper with the impressions of one of our correspondents in his article in this issue entitled "Notes from the World's Fair." It will be noticed that agreement of opinion exists on one point at least, namely, that the Canadian Building does no credit to Canada.

MESSRS. Dill & O'Hearn were recently given a contract for painting the exterior wood and iron work of one of the Toronto public schools. After the contract was completed, a Mr. Moore, who is alleged to be a rival contractor, charged Messrs. Dill & O'Hearn before the Public School Board with having violated the specifications by giving the building one instead of two coats of paint. A committee of the Board was appointed to investigate, and reported that they were of opinion that two coats of paint were not given to the whole of the work, and that as to any part of the work which might have received two coats it was done in a very hurried manner and not in accord with the intention of the specifications. The contractors admit that the work was hurried, but claim that otherwise it was properly done. When the report came before the Public School Board for consideration, it led to a warm discussion. The chairman created a sensation by stating that it had for a long time been a by-word in Toronto that work in connection with the public schools had been scamped, and that specifications were so drawn that certain favored contractors could secure the work. These remarks, reflecting severely upon the honesty of the Superintendent of School Buildings, were very properly resented by some members of the Board. The Superintendent is, we believe, above such conduct. The report of the Committee was adopted without the Superintendent being asked to report on the case, or explain his position in relation thereto —a course of action which must be deemed to be most unfair to the head of an important public department, more especially in view of the fact that the work had not been finally passed by the Superintendent and there was owing to the contractors on other contracts more than sufficient to cover any defects in the work It is alleged that the man who preferred the complaint had been detected in an attempt to scamp a contract which he had secured from the Board, and that his action in the present case was an attempt to get even with the Superintendent for having compelled compliance with the specifications.

AN ARCHITECT'S OPINION OF THE "CANADIAN ARCHITECT AND BUILDER."

Mr. F. J. Rastrick, the well known architect, of Hamilton, Ont., writes: After an examination of the last year's numbers of the CANADIAN ARCHITECT AND BUILDER, I wish to congratulate you upon the great improvement which has been attained. It has become quite an artistic publication, and one which is not excelled amongst the architectural publications of the United States or Great Britain.

TORONTO ESPLANADE IMPROVEMENT.

MR. Sankey's report to the City Engineer contains his plan for laying out the new water front on the bay, so as to provide public wharves that will give a favorable impression to visitors who enter Toronto first by this way; to arrange for heavy traffic on Lake Street and reserve sites for commercial buildings on the landward side of it; to bring street car accommodation by coverhead lines in connection with the ferries and lake steamers; and lastly, as the wharf accommodation provided is considerably more than double that now in use, to reserve for the public a large waterfront square surrounded on three sides by water.

The works proposed occupy the space from the Yonge Street wharf to the new pier of the Argonaut Rowing Club—practically from Yonge Street to York Street. There will be a new Yonge Street wharf more than three times the size of the present one. The new wharf will more properly speaking be a sold pier cribbed only on the outside and filled in firmly with earth. The front will be long enough to allow the longest lake steamer to lie without obstructing the passage of other vessels to and from the sides, which will be of somewhat greater length than the front. The pier will thus form a square of solid earth with a wharf all round. The space reserved for wharf room is 50 feet —20 feet for a gangway and 30 feet for wharf buildings. Behind the wharf building there will be a 40 feet road all around, leaving a central block, round which the road passes, which will be well adapted for a fruit market and cold storage warehouse. The ferry pier will be at the foot of York street and will have besides landings for the ferries, accommodation for steamers running in connection with the railways. The remaining space, about half the distance between Bay and York streets, will be occupied by what Mr. Sankey calls the "Harbour Square." This will be formed in the same way as the Yonge street wharf by external cribbing filled in with earth and will form an area, planted we may presume with trees, about 400 feet wide and running out for about the same distance or a little further into the bay.

To bring the public into communication with the water front it is proposed to form a loop of the street railway between York and Yonge streets bringing the lines down by inclined bridges from the level of Front street to that of Lake street.

In pointing out that the expense of constructing the wharves and harbour square will be small, Mr. Sankey says:—"It should not be more than the cost of the necessary cribbing; there is always a demand for a dumping ground near the centre of the city, and all the filling necessary can be got for nothing." It is however necessary that in constituting these works dumping grounds for the city, some discrimination should be used as to the nature of the material dumped. It will be of little use to provide the Harbour Square as a breathing ground for the people if its soil reeks pestilence. The filling in that has been going on all summer in front of the Union Station has been composed to a great extent of what it is no exaggeration to call garbage. The collection of tin cans, broken pots, vegetable tops, spoiled fruit, etc., which was carted to this spot showed it to be the sweepings of the city lanes. To cover it with a layer of earth made it little less offensive than before. The animal life that is generated from decay is said to be indifferent to burial, and it is probable that unless steps are taken at the beginning to prevent filling in the new works with anything but clean stuff we may expect the Harbour Square to be a resort more favorable to microbes of disease than to human beings.

ILLUSTRATIONS.

POST OFFICE, HALIFAX, NOVA SCOTIA.

THE building, which is constructed of freestone on a granite base, stands in a square opposite the Provincial Buildings. The exterior appearance is very satisfactory, but the interior effect and accommodation are less so. The architect of the building was Mr. David Sterling, of Halifax.

DETAILS FOR SMALL TOWN HOUSE.

These details are to accompany the design for a small town house published in the CANADIAN ARCHITECT AND BUILDER for September.

SUMMER RESIDENCE FOR MR. A. W. OGILVIE, MONTREAL.—A. C. HUTCHISON, ARCHITECT.

ST. JOSEPH'S CHURCH, OTTAWA.—W. E. DORAN, ARCHITECT.

QUESTIONS AND ANSWERS.

[Readers are invited to ask through this department for any information which they may require on lines consistent with the objects of the paper. Every effort will be made to furnish satisfactory answers to all such inquiries. Readers are requested to supply information which would assist us in our replies. The names and addresses of correspondents must accompany their communications, but not necessarily for publication.]

G. E. M., Toronto writes: How many pounds would there be in a bushel of white lime just from the kiln.

ANS.—About 70 pounds.

MONTREAL.

(Correspondence of the CANADIAN ARCHITECT AND BUILDER.)

The sentiments expressed in the following extract from a letter recently addressed by Mr. L. J. A. Papineau to the Cure of the parish of Notre Dame de Bousecours, Ottawa County, protesting against a proposal to substitute for a church in camparatively good repair an expensive edifice of more modern design, will no doubt strike a responsive chord in the breasts of many of your readers: "I have seen in Scandinavia many an old wooden church, of several centuries' existence, and which are as venerated as the lead temples of marble and mosaics in Italy. All throughout Europe they preserve all monuments, civil and religious; and the more so in proportion to their antiquity. In America, on the contrary, people's ambition is to destroy. Each generation seems desirous to pull down whatever their fathers have erected. In Canada, since a few years, it has become a mania to demolish churches and make everything new. For our rural churches there had grown a Canadian type; a long building of boulder masonry, bound by a mortar as hard as a cement, a triangular front and steep roof, arcaded doors and windows, plain, without superfluous ornaments, the shining roofs and steeple seen from afar in the sunlight, the long and sharp steeple ascending towards heaven, crowned by the cross and the Gallic cock. All these old monuments of our ancestors people are now hurrying to destruction, to replace them at fabulous prices by monstrous constructions which are neither gothic nor classical, but a mass of incongruities which may be called the Jesuitical order of architecture, such as is exemplified in so many churches of Spanish America and a few modern European. An agglomeration of pinnacles and caps which, grovelling low, are neither steeple nor dome, and in place of a tympanum display immense white flourishes and ribbons of stone which resembles the contortions of serpents in place of the triangle of Jehovah or the Trinity. We have a striking example of this barbaric transformation in the unfortunate chapel of Bonsecours in Montreal—the only temple left in that city of the colonization period—that venerable temple, which has been so shamefully altered both internally and externally. They have destroyed the many golden sculptures that once decorated the original parish church of 1645, and replaced them by horrible grey daubs worthy of penny theatres. I will not mention the elevator to the roof exhibitions. What a caricature they have made of the holy shrine."

Mr. Porteous, who was perhaps the oldest architect in Montreal, died in this city on the 28th August, at the advanced age of 82 years. Deceased was the designer of a large number of churches and factories. He superintended the construction and hanging of the lock gates of the Williamsburg and Cornwall canals, having been the inventor of an improved method of hanging such gates.

In olden times it was not unusual for the building of a cathedral to occupy a period of one or several hundred years. In our times, however, we are accustomed to see great structures rise as if by magic, and but a few years are required for the rearing of mighty cities. In contrast to this haste of modern times has been the building of St. Peter's Cathedral of this city, which is to be opened at Christmas. It has been under construction for a quarter of a century, not because it could not have been erected in a much shorter time, but because its progress was limited to the rate at which the necessary funds could be obtained. The building, as is generally known, is a model of St. Peter's at Rome, and is about one-third the size of the latter. The interior decorations are as yet incomplete.

HAMILTON.

(Correspondence of the CANADIAN ARCHITECT AND BUILDER.)

The old post office building on St. James street, which I have always regarded as one of the most creditable of the public buildings of the city, is sought to be occupied by the Associated Charities or the Wentworth Historical Society. I trust the latter Society's request may be preferred, as I should dislike exceedingly to see such a building given up to the uses of a soup kitchen.

The statue of the late Sir John A. Macdonald to be erected in this city, and of which an illustration appeared in the CANADIAN ARCHITECT AND BUILDER some months ago, is to be unveiled by the Premier of the Dominion, Sir John Thompson, early in November.

The Board of Works entered early in the year into a contract with Messrs. Robert Thompson & Co. to supply a certain quantity of lumber, at a certain price, for the use of the corporation. The Board having subsequently overdrawn its appropriation, the Mayor instructed the Street Commissioner to receive no further consignments of lumber. In consequence of this order, the contractors threaten to enter suit to compel the acceptance of the balance of material called for by the contract.

The present year has been a fairly active one for architects and builders, and the fact that a considerable increase in the city's population is reported by the assessors may be regarded as a favorable indication for the future.

NOTES FROM THE WORLD'S FAIR.

(By a Correspondent.)

What has been written in the American press about the building of the World's Fair would, if taken without a grain of salt, raise expectations after which the Kingdom of Heaven would be disappointing. But one becomes so accustomed to make light of any utterance of the American newspapers and to make due allowance for the conscientious enthusiasm of articles in the illustrated magazines, that, in spite of all that has been said, the Fair was not disappointing. It is in fact a great piece of designing and a triumph for its designers and the nation.

There is nothing in the natural shore to suggest the result obtained. It is an unbroken beach, sandy and barren. The arrangement of the ground appropriated to the Fair is a piece of pure design, and to whomever it first occurred to dig out a portion of the grounds and let in the water of the lake is due the feature which forms the essential beauty of the Fair and its essential advantage in beauty over other Expositions. The rest is perhaps no invention. Neither the idea of abandoning the old form of Exhibition building in iron and glass nor the material used in making other forms was new. But the completeness with which the scheme has been carried out makes this Exposition a new departure in Exposition building.

The "staff" with which the buildings are covered, a compound, chiefly of plaster of Paris and cement united with fibre, which was invented for the last Paris Exposition, has when set an appearance very like the white stone of which the chateaux of the Loire Valley are built. It is applied to a construction of iron and wood and the result is a building apparently made of stone. As to the buildings themselves, to read some writers on the subject one would think there never were such buildings, that now for the first and only time the world has seen perfect buildings. This is not precisely true; but for total effect the "White City" has been an opportunity in design which the world can seldom offer and of which the associated architects, acting in concert with a great landscape gardener, have taken good advantage. Partly by virtue of size, for the porticos of the Manufacturers' Building are 122 feet high and yet do not appear unduly large; partly by virtue of uniformity of colour and harmony of style; partly by dint of profusion of architectural features, such as domes, towers, pinnacles, colonnades and statuary, but chiefly by skillful disposition of the buildings and by the introduction of the final charm of water with its accompaniments of bridges, balustraded terraces, broad flights of white steps for landing in some parts and the dark contrast of overhanging trees, all planted, in others, the enlivenment of passing boats and of water fowl which swim about and break the water into many colours; the buildings as a whole form a piece of architectural landscape which realize Turner's pictures of Carthage and Ancient Italy. The architects have for once found themselves to some extent in the position of poets who, as Bacon says, may build for beauty only, as they build with small cost. I do not however, think, that any one can argue from these buildings a case for sham; for they cannot be called shams, being so obviously and openly ephemeral. The well regulated mind, which would loathe a sham in permanent work, can derive straightforward pleasure from these buildings and rather prefers in the case of a summer's show to know that the cost is not absurd. Moreover, part of the offensiveness of sham is the facility it affords for representing noble material in a base situation. The soul recoils from a marble front to a corner grocery store. But here no magnificence is out of place, provided it does not cost too much. So far from revolting from an impossible magnificence the imagination claims it as due from the material used, and resents instead a compassable severity which would really simulate stone. It is at any rate true I think that the less satisfactory buildings fail in the direction of the commonplace and matter of fact. The designers who have succeeded best have been those who have used to the greatest extent the freedom given by the material for a lavish use of columns, statuary and plastic decoration.

At one end of the Fair grounds apart from the Exhibition buildings are the States buildings, which represent the States and countries taking part in the Exposition, and contain the official apartments of their commissioners. On the whole it must be said that with the exception of some of the foreign buildings they form a sorry exhibition of designing, and one of the very worst is that representing Canada. Its triviality of design and barren ugliness were more tiring than ten hours in the picture gallery. Many of the States were led astray by their originality, but not so the Canadian designer: his originality was well in hand. Others thought more of displaying native material than of perfection of design. The Canadian designer displayed nothing but native ugliness. Among States' buildings of the United States the best are those which reproduce old examples. Massachusetts excels with a reproduction of the truly refined and beautiful John Hancock house. California has reproduced a Spanish Jesuit mission building, a large building which is used also for an exhibit from the State. New York, it was originally understood, intended to reproduce the Van Rensselaer Mansion on the Hudson opposite Albany. But New York has turned its back on the Dutch and proclaims itself in a present day fashion by a gorgeous Renaissance Club House, extravagantly finished, thickly carpeted and hung as to the walls with tapestry or silk. The stairs are of stone on concrete, with a marble dado, if I recollect rightly, and the economically minded visitor only breathes again on discovering that the handrail is of wood painted to imitate marble. All this for one summer's use is of course sinful. We may congratulate ourselves that the Dominion Government possesses more of the domestic virtue of thrift and that we are spared the pain of regret that the Canadian building must be pulled down. The English Government *more Anglicano*, have built their house solid and presented it to the Park Commissioners to serve some purpose in Jackson Park, after the Fair is over. And this, I believe, will be the only relic on the grounds left of the whole display.

It is hoped that copies of some of the fine groups of statuary will find their way into museums. But some of the best are colossal and others would lack their architectural and landscape setting.

For the buildings there is no further use; and, even if left, they would soon shed their beauty to the ground and stand as bare as trees in the autumn.

One wonders whether there will again be so great an Exposition. It is understood that the promoters of this Exposition will drop nearly half as much again as the entire cost of the Centennial Exposition, and what people can stand such an outlay?

However, there will be Expositions, and if the designers of the next will learn positive lessons from this as well as caution, may I be there to see.

TORONTO ART STUDENTS' LEAGUE.

The Toronto Art Students' League has resumed its regular meetings. Preliminary arrangements are already under way for what promises in January next to be the most interesting exhibit of the work of the members of the League that has ever been submitted to the public view.

RECENT PLUMBING PRACTICE.

Mr. Glenn Brown, F. A. I. A., who read a paper on the above subject at the recent International Congress of Architects, at Chicago, summed up the deductions to be drawn from all the experiments reviewed by him as follows:

1. That unventilated traps are liable to fail from either or both siphonage or back pressure.

2. That small traps should have vents the size of the trap, and the main vertical vent should be three inches in diameter in ordinary dwelling houses, and should be computed for larger houses.

3. Ventilated traps do not fail by either back-pressure or siphonage.

4. That ventilation through pipes of the proper size should be required in all specifications.

In the matter of methods of testing pipe-systems, the smoke and the peppermint test are of little service, as they do not represent any pressure. Filling the pipes with water or testing them with compressed air, the pressure showing on a gauge, are the only reliable methods.

Steam for heating purposes says the *Plumber and Decorator*, possesses an advantage over hot water in the case of its application where great inequalities and frequent alterations of level occur, and particularly when the boiler must be placed higher than the place to be heated. For buildings occupied at intervals steam is more effective than hot water in its rapid generation of heat.

USEFUL HINTS.

One gallon priming colors covers 50 square yards; white zinc, 30; white lead paint, 45; lead color, 50; black paint, 50; stone color, 44; yellow paint, 44; blue color, 45; bright emerald, 25; bronze green, 75.

To remove rust from nickel plate: Grease the rust stains with oil, and after a few days rub them thoroughly with a cloth moistened with ammonia. If any spots still remain, remove them with diluted hydrochloric acid and polish with tripoli.

It is stated that ordinary brick boiled in tar for about twelve hours, or until they are saturated with it, are increased about 30 per cent in weight, are much harder than common ones and unaffected by frosts and acids as well as perfectly waterproof. They form an excellent flooring for work shops or store rooms, particularly in chemical establishments.

Cement for Mosaic Cubes.—Soak isinglass in water till soft; then dissolve in proof spirits by means of a gentle heat. In two ounces of this mixture dissolve ten grains of ammoniacum and while still liquid, add half a drachm of mastic dissolved in three drachms of rectified spirits. Stir well together and put in bottles. Melt by standing the bottles in hot water and use directly.

At the Workmen's Exhibition recently held at the Agricultural Hall, London, some interesting examples of wall decoration by means of sand were shown. A plain coloured surface having been prepared the design is stencilled on with gold size or some other suitable sticky material—varnish allowed to partly dry would answer very well. Sand that has previously been coloured to the desired tints is then applied to the surface marked by the design to which it adheres, giving a very attractive appearance. Sand of several colors may be employed if desired.

Swiss Brick.—In Switzerland there is now being manufactured a glass brick, or a brown building block, formed or molded flask shape, with a short neck at each end, 8 inches in length, 6 inches in width, and 2½ inches in depth, with an air chamber through the center. The edges of the brick are covered, recessed or ribbed and grooved to receive when laid a suitable cement of plastic material of such character that after it has hardened it will constitute a suitable frame or setting to keep the entire mass, roof or wall solidly together. The forms or molds, there being two shapes, are pleasing to the eye, the line or ridges being clear and smooth, and of sufficient thickness or strength to stand a pressure of 150 to 200 pounds to the square foot.

Experiments with glass bricks for building purposes were begun in 1891 by Mr. Falconnier, an architect of Lyons. These bricks are hollow, being blown like ordinary bottles, and are given forms—such as cubes, hexagons, etc.—that permit of ready laying. A bituminous cement, with a base of asphalt, is used; the bricks serve as double windows, giving protection against both cold and heat: they are good insulators of humidity and noise, and they lend themselves readily to the decoration of buildings, either by their form or their colour. Many applications are forseen. The bricks are described as neater than marble for meat markets, and are especially adapted for hospitals, bath halls, hot houses, refrigerating establishments, and buildings in which absence of windows would be an advantage. A hot house of glass bricks, we are informed, costs about the same as an ordinary one, saves fuel and resists hail.

Among the processes for fireproofing to which the attention of the directors of the Berlin Exposition was recently drawn, and for which awards have been declared, are the following: For light tissues, consisting of sixteen pounds of ammonium sulphates, five pounds ammonium carbonate, four pounds of borax, six pounds boric acid, four pounds of starch—or one pound dextrine or one pound gelatine—and twenty-five gallons water, mixed together, heated to eighty-six degrees Fahrenheit, and the material impregnated with the mixture, centrifugated and dried, and then ironed as usual. One quarter of this mixture, costing only a few cents, is sufficient to impregnate fifteen yards of material. For certain materials, theatrical decorations, wood and furniture, thirty pounds of ammonium chloride are mixed with so much floated chalk as to give the mass consistency, and it is then heated to from 125° to 150° Fahrenheit; two coats of it by means of a brush. A pound of this, costing only a mere trifle, is sufficient to cover five square rods.

Steam-Pipe Joints.—The method of constructing steam-pipe joints at one of the Edison Electric Light Stations in Boston where the working pressure carried is 150 pounds per square inch, designed by William H. Gallison, is said to have given excellent results. The pipe is made of wrought iron, and the joints between contiguous sections of pipe are made by the use of cast-iron flanges. The pipe and flange are threaded, and the screw joint is first made in the usual way, care being taken that the thread on the pipe is of sufficient length to extend through the flange its full thickness. After being made up solid inside of the pipe at the extreme end is expanded by the use of a hammer, the metal being driven or riveted into the thread. The pipe is then put in a lathe, and the flange faced off throughout its whole surface; not only that of the cast-iron of the flange proper, but also that of the end of the pipe. The gasket which is used is made of copper, and care is taken that this extends through to the interior edge of the pipe as well as the surface of the flange.

Coatings for Preserving Stone.—The following formulæ for metallic cements are given by Mr. Grimand in *La Revue Practique des Travaux Publics*: Oxide of zinc dissolved in a solution of chloride has for a long time been used as a paint, and it serves as a base for the following cements: 1. Oxide of zinc, twenty kilogrammes; pulverized Lorraine cement stone, twenty kilogrammes; sandstone, ten kilogrammes. This cement must be tempered by a liquid composed of hydrochloric acid, twenty-two degress, B., ten litres; water, five litres; zinc white, three kilogrammes; ammonium chloride, 0·5 kilogrammes. 2. A cheaper cement can be obtained by mixing oxide of zinc, ten kilogrammes; pulverized Lorraine cement stone, twenty kilogrammes; sandstone five kilogrammes; and yellow ochre, 0·4 kilogrammes. This cement is tempered with the solution just given, diluted with five litres of water. For soft stone, a cement is made of oxide of zinc, ten kilogrammes; Lorraine cement stone, thirty kilogrammes; sandstone, ten kilogrammes; and yellow ochre, 0·3 kilogramme. Or the following formula may be used: Zinc white, five kilogrammes; plaster ten kilogrammes; Lorraine cement stone, ten kilogrammes; and yellow ochre, 0·5 kilogramme. If an extremely strong cement is desired, it can be prepared of oxide of zinc, ten kilogrammes; pulverized quartz, fifteen kilogrammes. For the last mentioned three cements, the liquid given above is used, only ten litres of water are added instead of five litres. These cements can be applied with a brush as a paint. Colours give give good results. The coating adheres perfectly to the stone, and gives it the appearance of a newly cut surface, and at the same time forms a protecting covering against the inclemency of the weather. The stone should be well cleaned before applying the paint, and, if necessary, several coats may be given.

Method of Measuring Bridge and Floor Vibrations.—Professor Steiner, of Prague, has perfected a method of accurately measuring bridge and floor vibrations by the aid of photography. His process, says *Le Genie Civil*, is a delicate one and is an application of the chrono-photographic process of M. E. J. Marey, of the Institute of France. He uses little glass balls, and these are strongly illuminated, either by the solar ray or by an electric arc light or a magnesium light. These balls give upon a photographic negative a clear and well defined point. To register vibrations one of these glass balls is fixed at the point to be examined, and the photographic apparatus then so set up that the image of the ball falls on the right edge of the plate. The plate is exposed at the moment the movement commences, and at the same time the camera is turned from right to left on a pivot. The negative then shows an undulating line which is the vibrations of the ball point in amplitude and duration to obtain a scale with which to read this undulating line, a second ball is suspended to a fixed point, to which is given a known rate of oscillation. The position of these two balls is such that their images coincide in a state of rest, and a comparison of the trace of the second ball as printed upon the line of the first on the negative gives the number of vibrations of the latter in a given time. It is possible, then, to place near the first ball a fixed scale, brilliantly illuminated like the ball itself, and as this scale appears on the negative, the amplitude of the oscillations can be measured at a glance. The measurements may be made either directly upon the print or from an enlargement made in the usual manner. To avoid the practical difficulty of making the images of the two balls coincide at the beginning of the operation, Professor Steiner says a pendulum may be made to oscillate before the source of illumination of the ball. The ball of the pendulum will pass before the light at regular and determined intervals, and the undulating line of the negative will be broke at distances corresponding to the duration of the oscillation of the pendulum. It is not important that the camera turns upon its axis with a uniform motion, and the speed of turning is likewise of little importance. The relations of the curves placed by the two balls will always remain the same. It is suggested that an apparatus of this kind would be useful in studying the vibration of the floors of buildings resting for some years on iron beams, especially when these floors are submitted to the rythmic shock of dancing.

THE ARTS AND CRAFTS.

This is what Mr. Crane says, in a recent issue of the *Magazine of Arts*, as to the connection which should exist between Arts and Crafts: "The designer—if designer pure and simple he is forced to remain—must never lose touch with the craftsman. It would be well, indeed, if he practiced some craft himself, as the technical conditions, peculiarities, perhaps difficulties, he would be sure to encounter, would tell him more than any words about it; and the practical experience and suggestions gained would certainly react most favorably upon his power to design. Before the evolution of our industrial epoch of sub-division of labour, machine industry, and centralized markets, the craftsman was his own designer. Handicrafts, in fact, did not exist apart from art, and the workshop training and apprenticeship was common to them all. Thus a painter began as a colour grinder, and went through all the technicalities of the studio or workshop before he became master of them. The system is so obviously sensible and sound that it seems strange it should ever have been departed from, and, in fact, it only was broken up by the pressure of the modern commercial system, and the domination of the money-making idea."

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.

PROCEEDINGS OF THE ANNUAL CONVENTION.

The Quebec Association of Architects met in annual convention in the Parliament buildings, Quebec, at 10 a. m. on Sept. 28th ult. There were present :—

Victor Roy, President ; J. Nelson, First Vice President ; H. Staveley, Second Vice President ; J. Z. Resther, Treasurer ; A. C. Hutchison, Secretary ; A. T. Taylor, J. L. Peachy, J. B. Resther, Theo. Daoust, H. Nelson, F. X. Berlinguet, Chas. Baillairgé, George Emile Tanguay, A. Gendron, J. Redmond and J. Bertrand.

In a brief address the President called the convention to order. Reports of the Treasurer and Auditors were received and adopted ; also the report of the Council, which was as follows :—

REPORT OF COUNCIL.

The Council beg to report that since the last annual meeting of the Association held in Montreal, fourteen meetings of Council have been held, the business at which was principally of a routine character.

The attendance at these meetings was as follows :—Alex. C. Hutchison, 14 ; J. Haynes, 12 ; A. T. Taylor, 11 ; J. Nelson, 9 ; A. F. Dunlop, 8 ; J. Z. Resther, 8 ; V. Roy, 8 ; J. P. Ouellet, 1 ; J. J. Browne, 1 ; H. Staveley, 0 ; H. M. Perrault, 0.

The small attendance of Messrs. Staveley and Ouellet, of Quebec, is accounted for by an understanding that to save expense they were only to be summoned when the business was urgent and that the late Mr. Brown, owing to an accident which happened to him early in the year was incapacitated from attending.

At the first meeting of Council held after the annual meeting, Messrs. F. X. Berlinguet and C. Baillairgé, of Quebec, and Messrs. A. T. Taylor, Joseph Haines and Alex. C. Hutchison, of Montreal, were appointed a Board of Examiners. This Board reported that at the semi-annual examinations held in Quebec on the 26th and 27th of January last three candidates, namely, Messrs. J. P. Ouellet and J. P. E. Dussault, of Quebec, and Mr. D. A. Monette, of Montreal, had presented themselves and succeeded in passing the final examinations prescribed by the Act of Incorporation and by-laws. Their names were consequently entered upon the register of the Association.

The Board also reported that at the semi-annual examinations held in Montreal on the 27th and 28th of July six candidates had presented themselves for matriculation examination, and that the following four had succeeded in passing, namely :—M. Helbronner, P. Sicotte, F. Peden and J. A. Deschamps.

Shortly after the last annual meeting, the Council, with a view to bring the members of the Association resident in Montreal together more frequently, arranged that as many of the members as could make it convenient to attend should meet and dine together once a month—these monthly dinners to be followed by a general meeting of the members for the reading of papers, lectures and discussions on subjects of interest to the profession. These monthly dinners and meetings were held from December to May ; at the meetings papers were read and lectures delivered as follows : "Truth in Art," A. T. Taylor ; "Westminster Abbey," A. T. Taylor ; "Archaeology," J. Venne ; two lectures on "French and English Gothic Architecture," illustrated by lime light, by A. C. Hutchison. At one of the meetings a discussion led by Mr. W. E. Doran took place on the Single Tax question. While the attendance at these meetings was not as good as the Council expected, they hope that if they are continued during the next winter season the members will avail themselves of the opportunity thus afforded them for social intercourse and instruction.

An attempt was made in January last to form classes for the instruction of students, but owing to the difficulty of obtaining instructors and the apathy of students, they were not carried out.

During the last session of the Legislature of Quebec, a bill was introduced by Mr. Auge respecting the privileges of labourers, mechanics, contractors and furnishers of materials. As the provisions of this bill if passed were likely to interfere with and hamper the obtaining of loans for the purpose of building, and would foster the growth of an inferior and irresponsible class of contractors, the Premier of the Government was communicated with and he was requested to use his influence in preventing the passing of the bill. The Council were assured that when the bill came up for discussion their objections to it would be presented. The bill, however, was withdrawn before discussion upon it took place.

In the month of January printed lists of the names of members on the Register of the Association at the beginning of the year were issued to all the members.

Shortly after coming into office of the present government of the Province of Quebec their attention was called, to the tariff of professional charges which had been prepared in accordance with the terms of the Act of Incorporation, and submitted to their predecessors for confirmation by the Lieutenant-Governor in Council. As this had not been done when they left office, the present Government shortly after they had assumed office was petitioned to have the tariff confirmed at an early date, and on the 24th of March last a deputation of seventeen members of the Association waited upon the Honorable Mr. Taillon, Premier, and urged the claims of the Association to have the tariff ratified. Though the deputation was well received and promised that the subject would have his early and careful consideration it still remains in abeyance and has not yet been rejected.

As a number of the members of the Association wished to have a copy of the tariff as prepared by the Council and submitted for approval to the Government, it was printed in French and English and distributed to all the members of the Association. At the same time circulars were issued containing suggestions for the conduct of competitions. The Council would respectfully urge upon the members to use their influence with any person or body promoting a competition to have it carried out in the manner suggested by the Council.

Early in the year the formation of a library of reference for members and students was taken into consideration. As a library placed in Montreal could only be of use to the members and students resident there, it was felt that it would be unfair to the members of the Association not resident in Montreal to devote any of the funds of the Association to such an object. Subscriptions in books and money were therefore solicited from members in Montreal, and in response to the appeal the sum of $120.00 was subscribed as follows :—V. Roy, $25.00 ; A. T. Taylor, $25.00 ; Alex. C. Hutchison, $25.00 ; A. Raza, $25.00 ; W. E. Doran, $10.00 ; J. Wright, $10.00.—$120

Donations of books were also received from C. Clift, J. Nelson, A. F. Dunlop, A. T. Taylor, C. St. Jean, J. Haynes, Mrs. J. Redpath.

With the money and books thus subscribed and with those previously donated by Mr. C. Baillairgé, of Quebec, the Council have now 107 volumes upon the shelves of the library, and as they still have an unexpended balance on hand, the number of books will shortly be increased and the nucleus of a good library of reference established.

The preparation of a suitable design for a diploma to be issued to the members who enter the Association by passing the examinations prescribed by the Act of Incorporation and By-laws has received the attention of the Council and they are pleased to report that after considerable delays the diplomas are now ready, and that they are being issued to the members entitled to receive them.

Your Council regret to report in August last the death of one of its members, Mr. John James Browne. The following resolution of condolence was adopted by the Council and a copy of the same transmitted to his widow and family :—

"That the Council put on record their deep regret at the loss by death of their confrere, Mr. John James Browne, whose name has been identified with the growth of the City of Montreal during the last thirty years, and whose vigor and energy gave promise of many years of usefulness to come. His untimely death is mourned by all his professional brethren. The Council would also express their sympathy with the widow and family in their great loss."

In view of the short time between the decease of Mr. Browne and the annual meeting the Council did not consider it necessary to fill his place in the Council by the appointment of another member.

The Secretary's statement of receipts and the Treasurer's report are herewith submitted. The whole of which is respectfully submitted.

The Treasurer's statement shows a balance on hand of $139.16.

ALEX. C. HUTCHISON, Secretary.

The following officers were elected for 1893-4 : J. Nelson, President ; Chas. Baillairgé, First Vice-President ; A. C. Hutchison, Second Vice-President ; J. Z. Resther, Treasurer ; Joseph Haines, Secretary ; Members of the Council—A. T. Taylor, A. Gendron, J. B. Bertrand, Eric Mann, J. Venne, George Emile Tanguay ; Auditors—Theo. Daoust and J. F. Peachy.

A large and richly framed photograph of the original members of Quebec, was presented to the Montreal members, who tendered them a hearty vote of thanks.

A number of the visitors were entertained at luncheon by a few of the Quebec members.

At 2 p. m. a second sitting of the convention took place, when the following paper was read by Mr. A. T. Taylor :

BRIEF NOTES ON THE ARCHITECTURE OF THE WORLD'S FAIR.

If you wish to realize to the fullest extent the power and potency of contrasts, go to Chicago, and from thence to the World's Fair. You will have shade and light personified. To pass from the noisy, dirty, half paved, half-baked chaotic city of Chicago, to the fair white city on the shores of Lake Michigan, with its lagoons and islands, pleasant winding walks, fountains, statuary and architecture, is like a translation from Purgatory to Paradise.

It is not often the happy lot of any members of our profession to be called upon to design an ideal city. The average modern city is not planned—like Topsy, it just grows, and we are only allowed to touch with the finger of beauty a spot here and there. One longs for the days of Pericles or Cæsar, or even those of the First Empire, when cities were laid out with beauty and effect and were an exquisite settings for noble gems of architecture.

When it was decided to grant Chicago her desire to be the host of the nations, it became incumbent upon her to take steps at once to arrange for the same in a worthy and fitting manner. The experiment was not new, for many previous exhibitions formed precedents for her guidance, but Chicago-like she determined to achieve a success which would at once leave all previous efforts hopelessly in the background. How this has been done remains to be seen. The directors of the Fair were fortunate in securing the services of Messrs. Burnham & Root, architects in Chicago, to formulate a general scheme for arranging the necessary buildings on the flat swamp of Jackson's Park ; and Mr. Olmsted, of New York, was also called in to prepare a scheme for laying out the grounds. With great wisdom it was decided to obtain the co-operation of the best architectural talent of the United States in designing the various buildings. Accordingly, Mr. Richard Hunt, Mr. G. B. Post, and Messrs. McKim, Mead and White, of New York, Messrs Peabody and Stearns, of Boston, Messrs. Van Brunt and Howe, of Kansas City, and Messrs. Henry Ives Cobb, S. S. Beman, W. H. B. Jenney, Adler & Sullivan and C. B. Atwood, of Chicago, and one lady, Miss Sophia B. Hayden, were selected for the work.

The general arrangement was mainly drawn up by Mr. Root, whose untimely death has robbed the profession of one of its brightest members. The conception was so grand and dignified that it was accepted with but little alteration, and the various buildings were then all located amongst the above named architects. It was considered advisable to adopt one style for the general exhibition buildings, so as to gain unity and harmoniousness of effect, and yet by bringing to bear upon the problem different minds, a variety and interest was obtained. The style adopted was a liberal phase of classic, ranging from the severe Greek to a florid Renaissance. Two important exceptions, however, were made, viz.: in the Fishery Building, in which a free treatment of Romanesque is adopted, and in the Transportation Building, which is orientally nondescript.

What probably strikes a visitor most of all, is the apparently substantial and permanent look of the buildings, and then follows the inevitable expression of regret that they are so soon to be demolished and fade away like a dream.

In the nature of things buildings for exhibition purposes have been more or less of a light, flimsy and evanescent character. Perhaps we may make an exception in favor of those of the last Paris Exhibition which were about the best hitherto. We may say as a general rule, however, that the exhibits were the attractions in previous exhibitions and not the buildings ; in this case it is the buildings and not the exhibits. It is an undoubted triumph for architecture, and it has opened the eyes of thousands to the possibilities which lie in the work of our profession, to which they were previously blind.

Doubtless many architects who visited the Fair sighed for such an opportunity of distinguishing themselves in design as had been afforded the architects who were chosen, but he that will be faithful in much must be also faithful in little, and genius can be shown in a nut shell as well as in a cathedral. If we are but true to our noble heritage, and to our splendid traditions, and true to our better selves, we will pander to no evil tastes of the age, but will design the smallest buildings we have as well as we know how, making them instinct with truth, beauty, fitness and grace.

Whatever may be the results of the Exhibition on the industrial life of the world, I am convinced of this, that the architecture of the Fair will have a powerful influence on the architecture of this continent for good or evil for some time to come. The style adopted will be the predominant one, and we may expect to see reproductions of the various buildings more or less spoilt, springing up all over the country. One of the gravest results which I fear, will be the bringing again into use of the plastic material called "staff" or a modification of it. It has been found such a pliable adaptive material, lending itself readily to any shape, form or mode of handling, that people will forget it is only justifiable in its use for buildings of a temporary nature, and will endeavor to use it for structures of a more permanent character, the more especially as the gigantic and monumental character of the style adopted for some of the buildings would be enormously expensive if carried out in stone and such like permanent material, and there will be a great temptation, which I am afraid will prove to some people irresistible, to obtain the effect by using this "staff" or composition, to the destruction of truth and genuine progress in architecture. If such be the case, then the World's Fair of 1893 will mark a black period in the annals of architecture. It is not so long ago since we emancipated ourselves from the shams of "compo" fronts and the falsehoods which had well nigh strangled our beloved art, and were endeavoring to work on honest lines with honest material. Let us determine that we will not again be brought into bondage, being well assured that no architecture worthy of the name can live, progress and flourish that is not true and honest in every part.

I have had enlarged the general plan of the disposition of the buildings, so that those of you who have not been able to visit it will be able to form some idea of its arrangement, and I have also brought a few views of some of the buildings ; but no plan or views or description can give you much idea of the charm of the whole—it is to be felt and absorbed gradually and cannot be expressed.

The Court of Honor, as it is called, is the great central feature of the general design extending from the lake up to the terminal station, and so arranged that visitors by rail as well as visitors by boat are at once introduced to the grandest spectacle of the exhibition and are profoundly impressed at the outset.

At the lake is a triumphal arch modelled on the Roman arches and flanked on each side by a well proportioned colonnade or peristyle, terminating in a well designed ornate building at each end.

At the terminal station end is the great Administration Building, intended to be the centre of the whole system and having a gilded dome soaring up into prominence. Down the centre of the Court is a large water basin encircled with elaborate balustrading, terraces and steps, having at one end a statue of the Republic 60 feet high, gilded, and at the other a highly ornate and florid Columbian fountain.

On the one side of the Court is the gigantic Manufactures and Liberal Arts Building, and the buildings for Electricity and Mining, and on the other the palaces for Agriculture and for Machinery, the whole forming a magnificent group. Of course to architectural students whose mission it is to criticize and probe and dissect, there is fair scope for criticism on many points. Exception has been taken to the buildings on the ground that in design externally they have no relation to the objects or exhibits they enclose, and were a few extraneous sculptures and frescos removed, the buildings could be all transposed without affecting them in the least, and could even be labelled Royal Palace, State House, Court of Justice, etc., and sustain the character well. There is truth in this criticism, but at the same time it must be borne in mind that the very buildings are themselves in the nature of exhibits, and that each architect vied with the other in producing a noble and magnificent building *per se*, and quite irrespective of its use.

It is manifestly impossible in this short paper to go into an exhaustive description or criticism of the buildings. Their general appearance and their virtues and faults are no doubt familiar to most of you. I can only touch on them in a cursory way, and by bringing the subject before you refresh your memories on perhaps some points.

It seems to me that the designers acted wisely in leaving the buildings for the most part the natural white color of the material. The most radical departure from this is in the Transportation Building, which cannot be said to be happy either in its design or in its color scheme. It is crude in color, unintelligible in motive, and ungraceful and disproportionate in its parts.

I can only speak in passing of the Women's Building designed by Miss Sophia B. Hayden, and which is most creditable to her. She stands, if I mistake not, in the proud position of being the first woman to design a building of such magnitude which has been executed, and it puts to the blush many of the secondary buildings on the ground, such as the United States Government Building, the Illinois State House, and others. We shall have to look to our laurels when our sisters enter into competition with us, and there seems no reason why women should not engage more largely in architectural designing, and the tendency I think is to do so.

Perhaps the building that is most satisfactory and pleasing is the Art Gallery, designed by Mr. Atwood, whom I had the pleasure of meeting. It is purely academic in its treatment—a severe form of Greek having been rigorously adopted. In its repose and quiet dignity, chasteness of detail, and simplicity of outline, it is very satisfactory and restful.

One cannot but be filled with admiration for those old Greeks who produced a style which reproduction thousands of years after cannot spoil, and whose translation into other purposes cannot quench the light of eternal beauty inherent in it.

Of the State Buildings I can only refer to one or two. Some of them have a strict relation in design to the State they represent, and are therefore fitting and pleasing ; of these the California building, the Idaho building, the Massachussets building, as well as those of Colorado and Washington, are worthy of mention. Dotted about in every variety of style and color and material, they presented a bewildering and picturesque appearance. The Illinois State House has the unenviable notoriety of being perhaps the worst building on the ground.

Amongst the buildings representing foreign countries England has a modest but tasteful building in the English domestic style, well finished and furnished. The German building is most interesting, being finished with the fantastic and floridly grotesque decoration outside and inside characteristic of some of the Mediæval German buildings.

Canada, I regret to say, does not shine in its building. It is inoffensive and sadly commonplace, and conspicuously uninteresting. It is the more to be regretted as the position allotted to it is good, and the opportunity one which ought to have been taken full advantage of. Inside it is sadly lacking ; whilst other buildings had comfortable quarters where any one could get rest in luxuriance and read the papers or write letters amidst inviting surroundings, the aim seems to have been in the Canadian building to make it as uninviting as possible. In justice it should however be said that the money available was quite inadequate for such a purpose.

The little Dutch house of Van Houtens' merits a passing word. The charming interior furnished with Dutch tiles, blue plates, old oak furniture, together with the quaint costumes of the attendants, make as pretty a picture as could be found on the grounds.

On the whole the treatment of the sculpture has been most effective and many of the subjects are of extreme beauty, but these would merit another paper. I would praise, however, the smaller subjects rather than the more gigantic.

The gilded statue of the Republic already referred to is very unsatisfactory—the back view especially being most ungraceful and stiff, and the whole rather coarse and unrefined.

The McMonnies' fountain, as it is called, which has been so much lauded, I must confess I could not like. It seemed to me melodramatic and very disproportionate, many of the figures being lanky and ungraceful and the details evidencing a want of balance and due elevation.

In a few months this white city, or city of white elephants, as it has been called, will have disappeared like a dream—only the Art building will be left as a memorial of the great Exhibition. If it has done nothing else it has proved the indomitable perseverance and skill of those who reared it. It has been a testimony of the ennobling influence of architecture and to the possibility that lies in the art for the magnificent expression of some of the highest emotions of man.

Mr. Chas. Baillairgé then read the following paper :

A PLEA FOR A CANADIAN SCHOOL OF ARCHITECTURE.

I had the satisfaction about this time last year, or during the annual meeting in Montreal of the Quebec Association of Architects, of visiting in your company the splendid new engineering buildings of the McGill University, since opened by His Excellency, the Governor General of Canada, on the occasion of the conversazione given by the Governor of that institution on the 24th of February last, to which I had the honor of being invited.

McGill has now endowed Canada with a school of theoretical and practical technology and engineering second to none on this continent, and equal in every respect to those of the older world, as at Kensington, England, at Aix, Angers, and St. Cyr, in France.

You will remember, gentlemen, and we have it from Professor Bovey's own utterances on the occasion, that he was given *carte blanche* by the promoters to go abroad and spare no expense in bringing together from any part of Europe, the United States and the world at large, machinery and models of the very latest design and excellence.

And yet this School of Engineering was if anything less urgent for Canada to have than a School of Architecture, which we should long ago have been endowed with by the directors of Laval University, had some of our

wealthy French Canadians came to the rescue, as has now been done by the munificent benefactors of McGill. I say it was less needed than a School of Architecture, for at this stage of our country's progress, our engineers do not require to go abroad for help or hints. In this respect we are now self sufficient, as even when the Victoria was run over the St. Lawrence, our Keefers were adequate to the task and there was no need of going to England for men unacquainted with our climate and who merely proved their common sense and prudence by adhering strictly to the Canadian engineers' design.

America has outstripped Europe in very many things: the 800 feet span railway bridge over the Niagara, the more stupendous one of double the span between New York and Brooklyn, The Frith of Forth, of Scotland, to be sure, in its turn outstrips the Brooklyn with its twin arches of 1700 feet, and leaves the Eiffel tower in the shade, but its very boldness of concept on was due to lessons taught on the Columbian continent, lessons from the United States and Canada, by our now nearly half a million miles of railway with their stupendous cantilevers reaching from cliff to cliff over rivers and ravines innumerable and of untold depth, across the Rockies, the Ne adas and the more than marvellous Colorado, and other heretofore so-called impracticable situations, but which our American engineers have mastered in spite of old world fogies pronouncing them impossible.

Nor need we in this respect allude to aught else than our own system of inland navigation which not only equals but surpasses anything of the kind in the old world.

Our engineers have not been slow to mould their minds, their works on the same vast scale as that of our waters, while European engineering has been dwarfed in some respects by having to deal with the narrower streams, the less precipitous rocks of the Eastern Hemisphere. We have the proof of this in our Quebec docks, where when looked down upon from the city ramparts, it makes one's heart sore to think of the millions that have been wasted in the construction of a jetty some 4000 feet in length, to enclose what? not as it should have done, a space commensurate with our increasing Canadian commerce, an extent of ground where a series of piers or wharves could have been built out southward from the jetty and made capable of affording berths for a score or more of ocean steamers, had the jetty been moved northward by 500 or a 1000 feet as it could and should have been; no, nothing of the kind, nothing but a mere strip, a few hundred feet, the veriest fraction of our comparatively immense estuary of the St. Charles at its confluence with the St. Lawrence, a basin where a vessel of any length can not even turn around in, but must back out of by the same route it comes in.

Had a Canadian engineer been entrusted with this work, such an anomaly, such a costly blunder, never could have occurred, and what is of concomitant importance, the engineers over the work, both resident and foreign, unacquainted as it is now evident they were with the severities of our climate, and with the stress against a dock wall exercised by such a semi-fluid material as the sand dredging with which the jetty is made up, and apparently entirely oblivious of the allowance to be made in a retaining wall for the surcharge brought to bear on it by the mountains of coal heaped upon the embankment, have made the walls so thin, so inadequate to stand the thrust, that they are now and have been ever since the filling in has been completed in the rear thereof, gradually and surely bulging outward to their eventual destruction, and tie rods are now being inserted through them and one hundred feet into the heart of the embankment where they are anchored to stay the ruin, while the unresisting nature of the made ground is such that the ties should have been taken through the 300 feet width of jetty and anchored to the opposite or north face or cribwork of the mole.

This subject of the strength of retaining walls is of vital importance, and that they are generally made of insufficient thickness to stand the thrust from behind is evidenced by the giving away of the revetment wall along Commercial street, Montreal, which, if of proper thickness, say not less than ⅓ the height, as if to bear the stress of water, and thicker where a surcharge is to be allowed for, should have lasted 100 years or more instead of 50, to say nothing of the walls of antiquity, many of which still stand solid and unyielding after a life of several thousand years.

Imported English engineering knowledge was again at fault, and where the climate could not be invoked or blamed for it, when from failing to test the nature of the ground by borings, as should have been done, the front wall of the Levis graving dock had to be removed 65 feet further inward or to the southward and the dock curtailed by so much in its length, an error requiring the construction of an otherwise unnecessary dam costing $18,000 and in other ways nearly doubling the cost of the improvement, while rendering the dock so much less frequently available to vessels of the length built now-a-days.

I have said, gentlemen, that we are now well provided for in the way of a professional engineering education, but we can not say as much for architecture. To be sure, a great step has lately been taken by the profession in this country, in forming an architectural association, and obliging would-be architects to submit to a thorough examination as to their technical requirements and fitness for the business.

Our friend Mortimer is also entitled to our suffrages for embarking on the courageous and arduous task, may it prove a paying one, of editing and publishing his now well known, well patronized journal of architecture and construction, styled THE CANADIAN ARCHITECT AND BUILDER. Members of the profession have entered, I am glad to say, on a course of theoretical and practical instruction for the benefit of students, and papers on pertinent subjects are read at meetings of the association in their rooms in Montreal, and re echoed through the length and breadth of the Dominion and abroad by he kindly efforts of the gentleman just alluded to, for the benefit of all. But something more is required to be done for students, aspirants to our ranks; a chair must be established in one of our universities with a paid professor having at his disposal the necessary models, the indispensable appliances for imparting knowledge of a technical and practical nature; just as for a course of physics, chemistry, electricity and the like, instruments and specimens are at hand for imparting a thorough knowledge of the sciences.

If no one can be found amongst us rich enough and patriotic to do the needful, our Government should be appealed to, to help Laval in this long talked of chair of architecture at the University, and what I am now about to add to these preliminary considerations will amply demonstrate the need of instruction in the theory and art of building. And engineers would, like their confrere architects, be amply benefited thereby; for the professions overlap in many instances, and in the same way that an arch tect must know something of engineering, as when building foundations in water, or when called on to design and carry out a viaduct, a light house, etc, so must the engineer trench upon the domain of the architect in the construction of a mill or manufactory, a bridge, an engine or power house for water works, electro motion, a grain or other elevator, a store for dockage purposes, a railway station, and the like.

During a professional career of now over 40 years as land surveyor, engineer and architect, I have had to design, estimate, cost and superintend the construction of very many structures of all kinds, small and large: dwelling houses, churches and presbyteries, the Laval University buildings, colleges, convents, asylums, hospitals, hotels, schools, theatres, mills, manufactories, etc.; and engaged as I have been in hundreds of arbitration cases, relating to defects of construction, as in the settlement of untold accounts for extras arising out of faults of omission and commission on the part of builders, architects and so-called engineers and others; I have had abundant opportunity to notice the great and unpardonable ignorance displayed in scores of instances, of the simplest rules of the constructive art.

There is nothing more usual for instance, with the bulk of our would-be architects and builders than to be totally ignorant of the fact that the strength of a beam or joist is as the square of its depth, and inversely as its length, though they can hardly help seeing without any calculation that the supporting power increases with the breadth.

Do they even know the meaning of the term "square of depth," or if so would they not see that whatever unit they add to the breadth of beam, a fraction of the same added to the height or depth of a joist would produce an equivalent effect. Thus, while to double the strength of a beam its depth remaining the same, its breadth must be double; the same increment of additional resistance is added to it by increasing its depth by four-tenths only, or a little more than one-third of its vertical height, with a saving of nearly two-thirds in the quantity and weight of the additional timber, and the same of course in dealing with iron or steel bearers or supporting bars of any kind. To treble the strength, the advantage is more apparent; it suffices to add not the double of four tenths, but only seven-tenths; while to quadruple the strength, the depth has only to be doubled, or trebled to make it nine times as resistant to any load it may have to support, and sixty-six and two-thirds per cent. of the material saved.

Of course there is a practical limit to thus adding to the height of beam to increase its strength; as, in the case of timber for instance the deeper beam must be cut from a larger and more expensive log, and if very deep, staying or lateral bridging must be introduced to prevent shearing, twisting or giving laterally. And again the depth of floors can not be indefinitely increased, the height between them decreased by so much, or the height of structure added to in a manner to make it more costly or of ungainly aspect. What is more usual in scores of dwelling houses and other buildings than to see the doors out of square, a table so much inclined that you cannot lay a pencil on it without its rolling off,—everything in the house in a word out of the perpendicular or out of level, and all this due to a settling of the centre of the structure attributable to sheer ignorance of the fact that the middle wall of a house should be of just double the strength of the outer walls; while in general not half so strong, or worse than that, no wall at all—a mere stud partition where the superposed head and foot sills and joists and other horizontally placed timbers crush and shrink both by their own weight and in the action of drying. Then there is the incident cracking of the plaster due to the settlement; and the unhorizontal lines of the ceilings and skirtings rendered more strikingly so by the skew to which the vertically hung papering has to be cut at top and bottom to fit the inequalities, and which to a sensitive and appreciative eye cannot but be a source of mental agony, to say nothing of the bodily inconvenience of such a structure and of the expense of cutting doors to suit, displacing locks, latches, etc.

These defects, this saving of the cost of a central wall or other adequate modes of support by cast or wrought iron columns and bearers resting directly the one on the other, or an incompressible stone or brickwork, are often due to the parsimony of the proprietor, or to his ignorance, and in total disregard of the advice of his architect or builder; and the structure remains a crying disgrace and reproach to all concerned in its erection, and a source of discomfort and torment, as everything unaesthetic generally is, to all people of fine and cultivated feelings.

But there is also to be guarded against, the sagging of a floor between the supporting walls; and to this end it often suffices to remember that every joist, as far as possible, or at least every second or alternate one, should stretch right through the structure from front to rear, and so as to rest on all three of the walls, the centre one as well as the two outer, i.e. on three points of support.

The strength of a joist is thus doubled and its tendency to sag at the centre of the vacant space thus reduced by 50%; its stiffness, as already said, being in the inverse ratio of its length. Nor must it be forgotten that when no more than two points of support can be had, or the beam not long enough to reach the full depth, then may its rigidity be increased 25% by thoroughly scaling it at one end in the wall, or by 50% when similarly sealed at both ends; not forgetting either that whatever weight the beam will bear at its centre, it will bear twice the weight when uniformly distributed over its length.

My advice to the profession is to design the work as it should be in every respect, and to so specify it, and let the plans and paper writing there remain to show and prove thereafter, in case of accident or damage to the building, that you proposed what you considered right and essential; leaving it to the proprietor, though under written protest, to cut and curtail as he may please, thin out the walls, shorten the joists or reduce their height, etc., etc., for the sake of false economy.

I have had examples of this more than once in my own practice, as when some 40 years ago I designed the then parish church of Beauport near Quebec. Each of the towers I had planned to have four walls—in fact to make absolute towers of them from the foundations to the base of the spires, the steeples reaching as they did to a height of 200 feet. The church wardens, in their economical wisdom, decided on leaving out the two inner walls of each of the towers and supporting the corresponding corners or sides of the spires on a single angle post or pillar.

The consequence was that each of the spires settled and leaned inwards and towards each other. When called on some years later to remedy the evil and blamed for such a mode of construction, I produced the original plans showing the four walls as at first proposed by me, when the work was finally carried out as intended by adding the omitted walls, and I was of course thereby relieved of all responsibility for the defect or what it cost to rectify the error of the former curate and church wardens.

I have already alluded to retaining walls and to the fact that they should generally be built as if to withstand the pressure of water. Now, this is a case where it is difficult to make most people understand the necessity of so great a thickness. So do not fail, I advise you one and all, to design your wall as it should be, and in case of failure due in after years to any want of breadth of base, your section will be there to bear you evidence that the fault is not to be laid at your door.

I have not always been faultless myself in this respect, wishing to economize the straightened means of such a poverty stricken place as old Quebec; but have long ago found out that it is all false economy, and that for no reason however plausible should anarchitect, or an engineer condescend to any such thing and then be blamed for it, while at the same time subjected to the annoyance of seeing such a wall from year to year, first gradually losing its batter and then slowly inclining over, and in ten to twenty years requiring reconstruction. But the thing becomes criminal when, as in the case of government structures, no consideration of economy need prevail, as when and only as late as last year the wing wall of St. John gate, Quebec, was rebuilt after being put up of inadequate strength, in 1868, of a thickness still inadequate and probably again requiring reconstruction before another twenty years are over.

Retaining walls will of course fail from other causes than mere thrust of the back filling, as where water can get into the filling or between the filling and the wall and freeze there from the omission of weepers to run it off, and the back filling should be rendered impermeable to water and thereby to frost by covering it over with some properly laid bituminous material through which water cannot penetrate.

There are other defects to be guarded against, as the bulging out of walls of certain structures by the stress of vaults and arches where not counteracted either by a proper thickness of the masonry only the strengthening thereof by buttresses, or loading from above by adding to the height and weight, or applying iron ties to counteract the spreading tendency, and bringing the walls together by heating and thus expanding every second tie and tightening up the nuts while the other ties remain undisturbed until in turn they be heated and curtailed in length by screwing up their nuts.

Appearances must also be attended to; the quoin or corner pillar of a building should not be less than that between any two adjoining openings, as when, as in the case of the Langelier block on the Grande Allée, Quebec, the door adjoins the gable wall. This defect should be corrected by widening the passage or even making a recess or a rounded corner in the adjoining room to allow of shifting the door in a way to get an increased width of pier.

Gentlemen, there is in our human nature an element of aestheticism: Certain proportions seem to be innate in us, planted there by the Creator, and irrespective of any tuition of the beautiful, they are so to say, engraved on the retina and thus rendered indissoluble. Likely this is due to the ratios in the human stature. We can all appreciate the true proportions. One is said to be too bulky for his height, too short, too stumpy; another too tall and slight; we do not like, we cannot bear to see a waist half way down the body, of which the normal height is at two-thirds or three-fifths from the ground we stand on. Even an illiterate person or a mere child will say of a building which is top heavy that it is ungainly, as of a person who is short-necked and his head resting on his shoulders. And this want of proportion of head to body is in no way better illustrated than when, in the arched or even square headed into a door or nitch or window, the impost moulding is set too high, as in the new side chapel of the Quebec Basilica where, the arched head of window being but one-fifth or thereabout of the total height, the architect should have kept down his impost by at least 4 to 5 inches below the centre of curvature to render the proportions satisfactory; and this, a fault of very common occurrence amongst architects and builders, should now that they are told of it, be strictly avoided in the future.

No one for instance likes to see a column divided in the centre, or its middle pointed at by an abutting cornice, or a plinth course, or by the head or transom of a door or gateway, or by the impost of an arched opening or by a notch of which either the top or bottom comes opposite the centre. On the contrary, if any such adjoining feature cuts the column, or abuts against it at just two-thirds the height above the base, one feels satisfied that the right proportions are observed.

Why are the reeds in the fluting of a column made just one-third the height of shaft? Try them at one-half and somehow or other you will not feel satisfied. Put two such columns side by side, one of which the fillings reach to half the height, the other to one third, and even the untutored eye will select the latter.

Have you ever seen a spire where if the height of angle minaret differ much from one-third the total attitude, the effect is pleasing to the eye. No, and any attempt to alter it materially is destructive of the effect; while on the other hand minarets and angle turrets reaching a have offat-roofed building are altogether out of place and objectless as introduced in a new house at corner of Daiquillon and St. Augustin streets of this city.

In the same way can we account, I believe for the rule laid down in classic architecture, that the first or main story of an edifice—the "rez de chausee" as they call it in France, must be about two thirds of the combined height of the two stories which surmount it, and an attic story one-third thereof or two thirds the height of the story which it crowns, while the window in the classic attic I allude to must be two-thirds the height of the openings of the regular stories below.

A door must be in some way proportionate to the human form when properly attired, as of a woman with her skirts, say in height from two to two and a half times its width and never its wigth anything like equal to its height.

A room is not satisfactory, it will please no one, not even those who are incapable of knowing why or of giving expression to their dislike, unless its length bears a certain ratio to breadth and height. Our new Parliament buildings, Quebec, are quite a failure in this respect, and to the great detriment of economy of space and comparative cost of building which is only 50 feet in depth from out to out leaving but 15 feet for rooms on either side the corridor, and making mere guts of any room with more than two windows in it, which is the case with most of the committee rooms, as well of those for draughting purposes, and Works and Lands Departments, whereas, had the depth been made 60 feet, the building would have cost but a trifle more for floors and roofs only, with the same walls, the rooms have been 20 feet in depth instead of 15 and the stairs have had a proper tread instead of the break-neck things they are.

Gentlemen, believe me, it is in no spirit of fault finding that I allude to these defects of construction, distribution and architecture; but it behooves us to educate our youth and public sentiment to a true appreciation of what is proper; and in the same way as I am now pointing out defects in buildings due to others than myself, so would I at all times be ready to admit the justice of any like criticism where I have been concerned.

Our new post office is, by general consent deemed top heavy—that is, there is too much masonry, too great a height of wall above the unduly shortened windows of the upper or attic story, and the contrary defect obtains to some extent in our new court house, where there is too little masonry in proportion to the size and number of the openings, which, had they been curtailed in height by just one foot or course of masonry would have restored the desired ratio "*le rapport entre les pleins et les vides*," as they say in France, improved the ratio of width to height of window; and maybe the "mezzanine openings under the roof had better have been omitted, or if essential to light and ventilation, hidden—"dissimulées," as the characteristic French expression has it—behind some ornamental open iron scroll work in imitation of the sculptured frieze of an entablature.

If I allude only to buildings in Quebec and do not reach to Montreal and elsewhere for comparison, it is certainly not that there be not something there to criticize, as is the too scant height above the windows of the sick wards of the new Victoria hospital at the foot of the mountain, the ungainliness of the N. D. Cathedral, the prison like structure at the S. E. corner of the Square and Great St. James street, the space uselessly taken up by the stair well and passages in the new City Hall; but because I have not the buildings in my mind's eye, and I am of opinion, gentlemen, that no better paper could be written by any one of you, none invited or solicited from your city architects of more realistic value to students of architecture, none educative of and conducive to a proper appreciation of the aesthetic on the part of the public at large, than a paper like this, written in a proper spirit, without any desire of fault finding, and which may be discussed to the mutual benefit of all.

What would Mansard say if he could now behold the variety of section given to the roof that bears his name? and in donne construction why do we so far depart from the beautiful proportions of that of the "Invalides" at Paris.

I will not say with the proverb that "there is luck in odd numbers," though I do not pretend to deny the fact; but there seems to be some reason for them even in the Scriptures, as in periods whether of weal or woe, famine or abundance, they are never counted in multitudes of 2, but where the odd unit invariably steps in to destroy the monotony of even numbers, and as well in breadth or horizontal magnitude, must these relations be observed as in the vertical already alluded to.

Try it and vary it as you will, the tower, the steeple must make some approach towards the one-third rule laid down of breadth of church facade, and so must the projecting or recessed central portion of any elevation of a building hold some relationship, some near approach to this same ratio of 1 and 2 to 3.

The old Beauport church already alluded to by me, and of which the facade and spire were over 200 feet in height, is a case in point, its towers like those of Notre Dame, of Paris, Westminster, of London, York, Strasburg, Amiens, Chartres, Tours, Bordeaux, Rheims, Orleans and others bore to the total width of frontage the due proportion and hence more pleasing to the eye; but the effect will now be destroyed in the restored structure by building the new towers, (with a view to not disturbing the interior) in a way to envelope the present ruins, thus increasing the distance between the towers without at the same time adding to their width and thus returning to the hybrid type of our Canadian church fronts with towers or imitation ones only one-quarter, one-fifth or less of the breadth of portal, instead of the majestic strength and beauty of the prototypes of ages.

Proportions must be adhered to or the thing becomes a failure, as in the case of the spire of the new church of St. J. B. of Quebec which, in spite of my forewarning, an old pupil of mine with Strasbourg and La Trinité, of Paris, before his eyes, has made an eyesore of from sheer want of 3 to 5 feet to be added to its diameter.

The odd unit is essential in almost every case. Do we not always have an opening, a door or window, a gateway, or the like, exactly in the central axis of a building, and even in a bridge or viaduct, do we not always seek, if possible to have a central span instead of a pier right in the middle of a river or a thoroughfare.

There are defects of space which may be remedied by optical illusion. If a structure be unavoidably low, avoid the too oft repeated horizontal lines of belting and cornices, and rather do the contrary and throw it into vertical lines, which have the effect of adding to the height. The vertical flutings of a column lengthen the shaft while horizontal lines or spirally wound ornaments curtail the height, bring down the vault or ceiling and dwarf the building, as is the case in the St. Patrick's church, Quebec, where the spirally guilt belt around the shaft brings down the ceiling by about 4 feet, and I wrote and advised the Fathers of this when but one column out of about a score or more had been done; but clerical pride and obstinacy prevailed as usual, and my uninterested warning remained unheeded.

Nor must we forget to observe the natural in all we do; not only must a post, a pillar or a column be stout and strong enough to support a structure, but it must appear to be. So, when the material for instance is iron, it should be known as such, and painted in a way to look like what it is, instead of being made to look like wood or stone, and thus create anxiety and doubt as to the fitness of its size for the burden it has to bear, and how often do we not see this elementary rule of ethics outraged by dissimulating the true material under a coat of imitation stone or marble, where such material, reduced to so narrow a diameter, would not only be obviously inadequate to sustain the superincumbent weight, but not even self supporting when so long or tall in proportion to its breadth. Montreal in this respect I have observed to be often at fault, as when wide openings for shop windows, etc., are surmounted by heavy piers or walls and the supporting beam which must necessarily be of wood or iron is painted in imitation of the stone facade, while a stone of such an inadequate height in ratio to its length, could not even support itself without breaking, thus rendering it absurd in such a position unless supported from below by iron or other columns visible to the eye from the outside.

Again what is evidently strong enough to bear its burden need not, should not, be supported when the supporting member is not required for distributive and decorative purposes. One of our young and talented Quebec architects has been guilty of this by his introduction of a heavy cut stone column right up to and under the very key stone of the attic arched central window of a new store on Dalhousie street, Quebec. This column is not required for support and as a mullion it should only have reached to the springing of the arch and the curved space above have been thrown into two sub arches and a spandrel.

There are defects of crowding too, which should be steadily avoided, as where the bay and other lateral openings of the new Langelier dwelling on Grande Allée are by a foot or more too close upon the central corps and entrance portico, and otherwise objectionably placed in a way to leave too much blank space beyond them.

Gentlemen, we want a School of Arts and Architecture, a school of architectural and constructive technology, or more than one, where our youth may be educated to the necessity and advisability of all these observances, and the thousands of dollars annually spent in making good the defects alluded to would ere this have paid for and maintained many such institutions on a permanent and continuous footing.

Relating to the sanitary element, made up of drainage, light, ventilation, heating, we are now pretty well off for Canadian and Forcign periodicals dealing with the subject, and I would merely remark on one of these heads, suiting the temperature to the requirements of the outer air, that I do not see why, as indicated in my paper "The Free and Liberal Ventilation of Sewers," read before the Royal Society in May, 1892, some means should not be devised and put into practice of adding to our comfort by cooling the inner air in summer in addition to heating it during cold weather. For, in the same way that the colder outer air is heated on its way to the interior of a building by being passed over heated pipes, in a similar manner can this outer air when too warm to suit the human system, be cooled down by passing it over the same pipes then filled with iced water instead of hot, or directly over a bed or stratum of ice; and how efficient this would prove is evidenced by the fact which all of you may have noticed as I have often done myself, that when on a warm day a breeze or current of air reaches one in the open after passing over the surface of the ice in the uninclosed van as we have them in Quebec, the decrease in temperature or coolness of the ambient air is thus most striking and agreeable.

And in other ways less costly can the air be cooled, as it always is in summer during a hot day when a shower of rain occurs, by robbing the air of its heat to become vapor; by following the same process, imitating nature in an artificial sprinkling kept up during the hottest hours of the day, or better still, where it can be afforded, by artificial rain around the house or opposite an open door or window, by conducting a pipe under sufficient pressure to rise to roof level, so that perforated along its length like the sprinkler of a watering can, it may distribute its contents over so much of the eaves as to suit the purposes required.

As to fire proofing, I would merely say that the subject is most pertinent,

and it is satisfactory to see that a very free use is now being made of iron joists and concrete floors; nor can we reasonably hope for much more than this, with brick partitions instead of lath and plaster, as no one will ever consent to dwell or even pass his or her office hours within a building entirely of stone and brick and iron. No one can nor will put up with with any such permanent and continuous discomfort for the sake of an eventuality which may never occur, or so seldom as not to warrant the expense of iron floors and stairs and doors and window sashes and their trimmings, thus surrounding one with ever chilling influences and more dangerous contact in cases of collision or of a slip or fall.

I have already reminded you in my last years' paper on "Escape from Buildings in Case of Fire" that there can be no real or reliable fire proofing unless all joists and beams and columns and other iron work be protected under a covering of terra cotta or some other non-conducting substance, as the mere furniture in any building—the carpets, curtains and upholstery, beds and bedding, clothes and linen and the like, the goods in storage, are always likely to produce such a heat as to cause wrought iron to shear and warp and give way, cast iron to crack and break, especially when reached by a column of water playing upon it from a fire engine.

I now beg to bring this conference to an end by reminding you of the advisability of providing for escape in case of fire as I am glad to see you are doing to some extent, as in the new Victoria Hospital and elsewhere, but having read a paper on the subject at your last meeting as just stated, I need not now further insist on the precautions to be taken.

No provision, I am sorry to say, has, as yet, been made for escape in case of fire from the six story new so-called Fortress Hotel recently erected in Quebec, though the interior of the horseshoe is admirably suited to a series of continuous galleries, one to each story onto which any one could step from his bedroom window and in a moment reach the street level by one or more light iron stairways, the whole in no way disagreeably obtrusive to the eye. It is to be regretted also that this otherwise elaborate building should be disfigured by an ogee roofed turret instead of conical, like all the others, springing from the apex of the roof over the main entrance on des Carriere st. where it is altogether out of place to have one pyramid on top of another. The upper angle of the main building also obtrudes itself offensively to the eye in awkward proximity to the roof just alluded to, and which to hide the defect and ease off the difference in height between the kitchen wing and main building should have been made just one story higher than it is. The angle turrets, one at corner of des Carrieres and St. Lewis streets and the two at the south west end of building, do not produce the good effect they would had they been made like others to stand out from the angle instead of coming flush with it, but the greatest defect and eyesore so far, contrary to all rules of ethics and not to be for a moment tolerated by even the most uneducated eye, is the heavy stone gablet rising from the eastern front towards the St. Lawrence and resting partly on a pier and partly over an opening or window which in common sense should be if required, in some way made to look like the remainder of the supporting piers.

After the reading of the above paper, the delegates visited the new Frontenac Hotel, Garrison Club, etc. Carriages were in waiting to take them to see the ancient Beauport church, after the inspection of which they were royally entertained by Mr. Francois Parant, ex-Mayor of Beauport, in the old home of Montcalm.

THE BANQUET.

After the first toast, that of The Queen, had been duly honored, Mr. Roy, the retiring President, proposed the toast of the Government of Quebec, which was received enthusiastically. Hon. T. Chase Casgrain, Attorney General of the Province, being called upon to respond, said (translated from the French):

Mr. President and gentlemen: I thank you very much for having drank the toast of the Government of Quebec. I must tell you that the health of the Government of Quebec is at present excellent, notwithstanding that my friend Mr. Barthe here says to-night in his paper that it is a moribund government. I thank you for your kindness in inviting the members of the Government to assist at this sumptuous banquet. To Mr. Nantel and myself it is certainly a great pleasure to be among you; and I have been charged particularly by the Premier to say that were it not for his engagement in Montreal in connection with the reception of His Excellency the Governor General he would be here to-night.

I think history, in giving us an account of the building of the Tower of Babel, for the first time speaks of architects. We are told this was an enterprise which had to be abandoned owing to the confusion of tongues. To-night, however, we have no Tower of Bable to construct: there is no confusion of languages, no confusion of ideas, no confusion of any sort; but the large attendance and the look of contentment depicted in every face are indicative of the good will and harmony which exist among the members of your profession.

I know you will follow the example of your ancestors, who, I have heard it said, even in the time of Solomon, charged very moderate fees for their services. I have found out, since I became a member of the Executive, and since I have had to do with architects, that their prices are extremely modest. Another thing that I have had the pleasure of ascertaining is, that "ye olden time" architects had no tariff; and I am glad to see that you of the present day follow in their footsteps in this respect. I speak as a man of experience on tariffs. We impose on the lawyers a tariff, force them to accept a tariff, and what is the consequence? To-day lawyers cannot charge more than the tariff nor less than the tariff: they are bound by it. As a result, if a lawyer go to Ottawa to plead a case he cannot charge more than five dollars, and if we had no tariff, he would probably charge five hundred dollars: so there is no advantage there. Now, if you had a tariff, you would be in the same position: you could not charge more than the tariff, although sometimes you would feel inclined to do so. I am sure it would be so injurious to you that you would not be inclined to offer such a banquet as you have this evening. Gentlemen, don't make a tariff. In making a tariff you make a rope with which to hang yourselves. I would like to be able to convince you that a tariff would not be productive of the good which a great many of you would expect to see flow from it.

I shall not prolong my remarks, but would say, however, that you have shewn us an attention of which we should show our appreciation; and I can assure you that when you come before the Government with demands that are just and reasonable—I see my friend Mr. Berlinguet looking at me as if to remind me that I should not promise too freely—when you do come with demands such as you have made heretofore, you will find in my colleague, Mr. Nantel, a minister ready to give your profession that which all professions have in the Province of Quebec.

Hon. Mr. Nantel, Commissioner of Public Works, being then called upon, said (translated from the French):

Mr. President and Gentlemen: Like my colleague, the Attorney General, I am sensible of your kindness in inviting me as a member of the Government to attend the annual dinner of your Association. Like him also I understand the importance of this Association of Architects; I understand its importance from the point of view of the benefits which it will confer on the profession in general and on the individual member thereof.

I will not say very much to you of the tariff, because my colleague has told you what he thinks of it. His remarks as to the lawyer's tariff was certainly news to me, and at the same time you; and you must have been surprised to hear that these gentlemen were willing to renounce their tariff. I am sure the lawyers feel very much embarrassed about this. In this connection I am reminded of the fable of LaFontaine, in which he tells us of a fox who, having been deprived of his tail, tried to convince all his fellow foxes of the uselessness of this valuable appendage. The lawyers see themselves menaced in the profession of their tariff, because it is quite clear this tariff cannot be maintained; and should they in advance preach the inutility of tariffs for the other professions, they would be even more foxy than they are supposed to be.

Now to be a little serious, my advice to you is: Do not do as he says, but do as he does, and have a tariff. Have a tariff as other professions have, and as your profession has in almost every other country.

The profession of architect is one which, in every country and among every people which has been blest with civilization, has ranked high. Architects have always been the pioneers of good taste, prosperity and progress. Architecture is not only one of the fine arts, but also a science. It is not only useful, but is indispensable; and it has been said—and with good reason—that in judging the architecture of a country, we judge the degree of prosperity which they have attained, and of the civilization which exists among its people.

Gentlemen, you have formed yourselves into an association, and I for one entirely approve of it. In association is strength; for it is the union of all the individual forces in a great whole. The idea of associations is particularly strong in this country, where men in every path of life are united in associations for the better attainment of their ends as individuals; and associations are and will be respected so long as each individual does his own share and is prepared to often sacrifice his own particular interests for the general good. You, gentlemen, have taken the means of making yourselves respected, and will, no doubt, continue in the course you have up to the present been pursuing. Be great, be strong, be powerful: it is your right. On the other hand, you have certain duties to perform, and among the most important is the improvement of the means of studying your profession. It is your duty to elevate the standard of your profession, and have it do here what it has done in the great countries of Europe— in France, in Italy, in Germany, in England—and we may say with candor, in the United States. No doubt we find there specimens of architecture which are somewhat uncouth, but we also find there grandeur, purity and above all, originality. We have there evidence of accurate study of the great architects, who alone possessed the true aesthetic taste. In the United States they make strenuous efforts to approach the Grecian style of architecture as being the standard; and in Europe they find that the nearer they approach the Grecian style the more perfect are the architectural creations.

We have seen with great pleasure in the newspapers that there is question of founding a chair of architecture which will be affiliated to one of the existing universities, either in Montreal or Quebec. This is a grand idea; and I hope you will push it to a successful issue.

We need reform in the mode of building, and particularly in the mode of constructing houses in the cities and in the suburbs of the cities of this province. I might mention specially the suburbs of Montreal. When in Minneapolis some years ago, I could not but admire the style in which the houses in the outlying portions of the city are built. There they begin by making ditches for irrigation purposes, by planting trees, by levelling the ground, and so on, till the house with its surroundings is a thing of beauty to look upon. In Montreal, for instance, what do we see? Buildings put up in a field, without even any provision for drainage being made, and we know to what it gives rise from a sanitary point of view. I think architects should combine with the municipal authorities to do their utmost to protect the community against these abuses. Sufficient attention is not at present paid to the laws of hygiene by a great number of architects. I must say, however, that students of the

profession have not the facilities for studying up the subject which they should have.

With a chair of architecture established in one of our universities you will be in a position to force your pupils to make serious studies, not only in architecture proper, but also in a number of other branches which to-day are very intimately connected with architecture. By means of such a chair there will be uniformity in your studies, and students, on the completion of their course, will be better fitted for the important work which lies before them.

The vocation of architect is a great vocation. Only the full strength and energy of great talents can in this path attain success. Unfortunately, in this country, particularly among French Canadians, resources are very limited. We have not such chairs of teaching as our English speaking compatriots have. They have received noble assistance from some of their wealthy men, and I only hope that some of these days a Stephen, a McIntyre, a Smith or a McDonald among us, will donate $50,000 for the founding of a chair of architecture. This is desirable and, no doubt, will come, and our people will know how to profit by it.

I cannot further prolong my remarks; but before closing, I would say, as my colleague has already said, you may count on the Government when the question of the tariff will come up to consider it with care and to carry it out. I think I can say tath without compromising the Government.

I again thank you, gentlemen, for the kind invitation which you extended to us. Rest assured it shall be warmly remembered by us; and if there is any way in which we can be of assistance in the development of your Association, you may rely upon us to do all we can consistent with the duties of our position.

Mr. Roy (translated): Mr. President and gentlemen, I feel the necessity of answering some of the remarks let fall by the Honorable Attorney-General, particularly when he suggests to us the advisability of abandoning our idea of a tariff. As the retiring president, I feel there rests with me a responsibility, and this responsibility weighs as heavily to-day as it did during the past year, to see this object carried to a successful issue. I have made efforts to have this tariff ratified by the Government of the day, knowing in advance that what we asked was not of a nature to injure the present Government, but, on the contrary, of a nature to render it aid and support; because the question of a tariff for architects is not like the question of a tariff for doctors, lawyers and notaries. The tariff that we ask to have approved by the Government is one that has existed for a great many years. There is no doubt as to the future, there is no fear that there will be any abuse. What we ask is simply a recognition of the value of the services of an architect, and this is the value established by the courts, and by the means save us from some of the difficulties under which we have labored here in the Province, and particularly before the formation of our association. I must say that since that time whenever we have been called upon in court to value the services of an architect, the court has gone with us. The question is always put to the architect who is a witness: Do you beloog to the Architects' Association? Now, what does this mean? It means that the opinions of those who belong to an association recognized by the law is taken in preference to the opinion of one who is not a member. The tariff which we wish to have accepted by the Government is no different from that recognized every day by the courts. It might be said, well, if it is recognized by the courts, what is your reason for desiring so much to have it sanctioned by the Government? Well, the great advantage which the sanction of the Government would give is, that it would obviate the necessity of our going to the trouble and expense of producing a number of witnesses to prove our charges as being fair and just. The ratification which we ask, and which we will have, if not from this Government, from another, would in this manner be of immense benefit to us. The idea of a tariff was mooted and took form under the existence of another government: it has been kept in abeyance for a long while; but I hope and trust this Government will not neglect to advance it.

I thank the members of the Government present here this evening, and particularly Mr. Nantel, who manifested more good will towards us than his colleague, the Attorney-General. The latter gentleman, however, improved somewhat as he went on, and he may finish by being very good. That is, at all events, the hope of the Association. We ask nothing exorbitant. The proposed tariff is one which is recognized as reasonable and just in all the countries of Europe, France, Germany, Italy, England and also by the United States and Canada. In our Province, however, it is not recognized by the law. That is the only difference between our tariff and the tariffs existing everywhere else. As I said before, we must have this tariff sanctioned, and if not from the present government, from another one.

The President then proposed the toast of the Association of Architects of the Province of Ontario, and there being no member of that association present, Mr. Berlinguet was called upon to respond, which he did in a few well chosen remarks.

The Press was proposed by Mr. Baillairgé, who took occasion to say a few words commendatory of the work of the CANADIAN ARCHITECT AND BUILDER, and requested Mr. J. B. Mortimer to respond to the toast, which he did. He was followed by Dr. G. Stuart, editor of the *Morning Chronicle*, Mr. Lavasseur representing *L'Evenement*, Mr. Carrel, of the *Daily Telegraph*, and Mr. Barthe, of *L'Electeur*.

Honorable T. Chase Casgrain, in rising to propose the toast of the Province of Quebec Association of Architects, said:

Mr. Chairman and gentlemen:—It is my privilege it seems and also my pleasure to move the last toast upon the list, the Province of Quebec Association of Architects. I may tell you, gentlemen, that although in my remarks a minute ago I, to certain minds, seemed unfavorable to the Association of Architects, I certainly feel very warmly towards them. And if you knew what good friends I have among the architects of Quebec, I might mention Mr. Baillairgé, Mr. Bertrand and Mr. Berlinguet, you would say that I could not but feel very warmly, not only towards the individual members of your body, but also towards the association itself. I am very happy to see that you have been for a certain number of years formed into an association; and really I see no good reason why, among all the liberal professions, the profession of architecture should not also form an association in the Province of Quebec. The members of every profession seem now to be forming themselves into associations, and certainly, if the notaries, the doctors and the lawyers have the right to form close corporations, there is no reason why the architects should not also become a corporation and an association.

The question which at present seems to be of the greatest import to the architects, I may say this from what I heard fall from the lips of my friend, Mr. Roy, who even threatened the Government, is the question of a tariff. The question: is a tariff required? is the principal question now upon the tapis. This is the great question of the day. I do not know whether or not there is any question of a tariff reform among the architects. It was hinted that I am opposed to the architects' tariff being sanctioned by the Government. Now, this is not at all true, and I am going to make some very plain statements, as politicians always do, upon this most important subject. You need not think I am going to beat around the bush, or that I am going to say things I do not intend to say or do not mean: I am going to be very explicit, as you will see when I am through.

You all know that since we have had the great pleasure and the great honor of administering the affairs of the province of Quebec, we have been kept very busy by our friends on the other side of the House. We have been obliged to fight our battle. We have been in power only eighteen months, and of course we have dealt with very important questions. The question of the architect is an important question; but we have dealt with very important questions; and, to tell the truth, we have not been able yet to consider this plan of tariff. Other tariffs, for instance that of the physicians, have come before the house, but up to the present not on account of any ill-feeling on the part of the Government towards the medical profession, but on account of the opinion which prevails that the country is not yet ready for it, we have not been able to sanction the tariff of the medical profession. Why? I do not know the reason. Why is it that the House will not allow us to do so? I cannot say. You will understand that if we have not yet taken up this question of a tariff for the architects, without wishing in any way to say anything disrespectful to the members of your profession, it is because we have had to deal with matters which were considered of more importance. We have not so far been able to come to it on the list, and therefore the Government has said neither yea or nay on it. We have it under consideration now; and, of course, as you know, governments generally keep questions of this kind under consideration for some time, and especially the good old Conservative party. But when we make a decision, you know that that decision is generally right, although it takes us a long while to come to the point.

Now, why is it, if the lawyers have a tariff, that the architects, who certainly belong to a liberal profession, should not also have a tariff? That is the question which I, as an individual, put to myself. Is there any reason, any moral reason, any political reason, why the architects should not have a tariff? Mind you, gentlemen, I am speaking for myself; I am not speaking as a member of the Government. I am not in any way binding the Government to any policy. Now, I may tell you this, if I am allowed to give you any advice—and this advice is all the better that it is not paid for; it is disinterested advice—when you frame a tariff, do not make it too high. Do you know what happened in the House to-day? We lawyers have a tariff, and we are suffering under the effect of that tariff. Our business is decreasing every day on account of that tariff being too high; and we have the threat that was made last year in the House that if our tariff was not reduced the House would take it into its hands to change the law so as not to allow us to make our own tariff, but to have it made by the Lieutenant Governor in Council or by the House itself. I understand that when an architect presents his bill before a court of law to have judgment rendered upon it that any member of your association can be brought up to swear that the charges made are just and equitable, and are charges which should be made upon certain works. Now, I would ask—speaking, mark you, simply as an individual—what would be the difference if you had a tariff sanctioned by the Lieutenant Governor in Council and forming part of our law? The only difference would be that instead of bringing up ten or fifteen witnesses to prove the charges contained in the bill you would

simply produce the tariff to show that your charges were not too high. This would be of great use to citizens and to the general public. Now, I think my friend, Mr. Roy, will concede that I understand this question, and that I am not against the architects. I have some arguments in favor of the sanctioning of the tariff; and I may say the only argument, if it is an argument at all against it, is that if the tariff is too high, the House will not bear us out in sanctioning it, but perhaps take upon itself to make a tariff or to abolish all tariffs in the Province of Quebec. You understand from what I am saying that this question is one of importance not only to architects but also to the Government and the country at large. It is a matter which deserves to be discussed from every point of view. Looking at it in this way, you will see why it is that up to the present the government has not seen its way to sanctioning this tariff. I know you will believe me when I say it; that this is the reason why the tariff of the architects has not been adopted so far.

Mr. Roy: you have been thinking too long.

Mr. Casgrain: That may be, but, on the other hand, you may rest assured that if we had not reason to fear that we might be checked by the House, it would be carried through. The House of course represents the Province, and until you convince the people of this Province that your tariff is what it should be, you will not be able to get it sanctioned by the Government or any Government which may come after us. It will be practically impossible, because we are subject to the rulings of the House, and I say now unless your tariff is reasonable,—and I think the one laid before us now is reasonable—and that the House is convinced that it is reasonable, it will not carry. I can say that you are greatly mistaken if you think that in the Government as it stands to-day you have any men who are against the tariff. If you will allow us to take our own time, if you will allow us to convince those who are not our supporters, I think you will achieve your end, and in a short time you will be able to applaud us even more enthusiastically than you have done to-night, although, I must say, you have received us with all due honors. But this, perhaps is drawing away from the subject upon which I began to speak.

I will now move that this toast be drank with all honors, and I hope and trust that your Association will always be found in the vanguard of progress, and that within a very short time you will achieve all the ends which you have in view, and as an individual, I hope your tariff will within a brief period of time be sanctioned by the Lieutenant Governor in Council.

Mr. Hutchison, Secretary of the Association, in response to this toast, said:

Mr. Chairman and Gentlemen, our Association is yet a young Association. It is only a few years since we appeared before the Legislature of this Province to ask for an act of incorporation. Now, I take it that in asking for such an act there were two objects in view, one of a professional or personal character, the other of a public character. Let us take the first one. It was in the interest of individual members of the profession scattered in the cities of Montreal and Quebec, scarcely knowing one another and having no interests in common, that they should by means of this association be brought into closer relations with one another. I think that object has certainly been accomplished in a very great degree. Since the formation of this association all the architects of Montreal have become well acquainted with one another as well as with the members from Quebec, who, before the passing of this act, were almost unknown to them. It has also had the effect of bringing closer to us the Association of Ontario, composed of men whom we did not know at all professionally.

Probably the second object under the personal and professional head might be this tariff that we have heard so much about to-night. I know that with a great many members the ratification of the tariff which has been prepared and submitted to the Government seems to be considered of very prime importance. Now, while it is important, I can hardly admit myself that it is of the importance with which some seem to invest it. Practically, a similar tariff has heretofore been in operation, though not legalized. It is the same tariff that applies in every country that I know where a tariff exists. France, England, British Columbia, Ontario have practically the same tariff as the one we have presented to the Government for ratification.

I think our tariff differs somewhat from the other tariffs referred to to-night. Take, for instance, that of the legal profession. If I understand it, the lawyer is bound to charge according to the tariff. Now, in our project it is distinctly provided that the tariff be not binding upon architects. An architect may make any other arrangement he pleases. It is simply a legal protection, so that when a question of charges arises in court we will be in a position to establish that the fees charged are legal. That is about all the good it will be to the profession.

From remarks which I have sometimes heard from some of our members, I judge that some supposed that when the Association of Architects was formed they were to get material benefit or profit from it. That is altogether wide of the mark. It never entered into my head, and I do not think it entered into the minds of any of the promoters of the association that the mere fact of the existence of an association such as we have got should be of any material benefit. I for one should oppose anything like trying to bring every man to the same level. I hope there is no one of our members who imagines that any act is going to bring the low high or the high to the low. Therefore, if the association has not met the expectations of some in this respect, I do not think it is any fault of the association.

Now, Mr. Chairman, in regard to the second object that we had in asking for an act of incorporation, the public interest. The art of building has become such a complicated affair now-a-days, that the structures that are being erected are of such a nature that a person to be a properly qualified architect requires a knowledge covering a very wide field in the sciences and arts. It requires a great deal of skill to be a good architect; and going before the legislature and getting this act was to prevent the public being imposed upon by parties who are not properly qualified. From this point of view it is certainly of much more interest to the public than to us of the profession. Now-a-days an architect requires not only artistic training for his calling, but he also requires a scientific training. The artistic and the scientific should overlap. There is so much steel and iron entering into our buildings that an architect requires a knowledge of the quality, strength and resisting power of these materials, which thirty years ago would not have been thought of. There is also so much to be known about hygiene that an architect requires to be posted on sanitary engineering. Electricity is making such advances, and is coming into such general use, that an architect must be able to wire a building and must know how to put electric plant in. Of course he may call in engineers to assist in all this; but at the same time he will be in a much better position if he be qualified to direct these works himself. The education of thirty years ago is nowhere to-day. But leaving aside all that, architects are called upon to design so many different sorts of buildings, such as mills and that sort of thing, that a familiarity with machinery is of the utmost importance in order to enable them to do their work satisfactorily. I find in the course of my professional work that I am called upon to build mills, and I have to have as much knowledge of the laying out of machinery as a millwright. As a guarantee to the public who have to employ architects we should have men properly qualified. Our act of incorporation provides that all persons who enter the profession after the passing of the act should previously pass an examination to show that they are properly qualified for the profession. Before entering the profession a young man has to show that he has had sufficient preliminary training. This has been faithfully carried out. In fixing the standard for the final examinations a very high standard has been fixed; I hope it will become still higher, and so far only four men have been able to reach it. As I have already said, in the interests of the public it is necessary that we should have properly qualified men; and one deficiency which still remains in our system is the lack of means of training aspirants to the profession. We have so far no school or means of giving men wishing to follow this profession a proper training; and as I have before advocated, I think it is one of the essential things in connection with our association to devise some means by which the necessary education can be obtained. It is true we have already made representations to McGill College; and it has often been talked about that Laval University should establish a chair. McGill University, through the munificence of some gentlemen of Montreal, has one of the best scientifically equipped colleges in America, and it lacks very little to make it most efficient for the special training required for our work. But while Laval and McGill might establish chairs of architecture, the requirements would not altogether be met. There will always be a great number of young men who will enter the profession by entering architects' offices as students; and to give these young men the proper instruction it will be necessary to have lectures given either in connection with the universities or in connection with our association itself. I think most of the gentlemen present know that I have tried hard during the last two winters to establish classes for the instruction of our young men. They have not, however, met with the success that I had hoped for them; but I trust that by sticking at the work we will yet get it established on a good basis. It should be compulsory on every young man entering an office to attend a course of lectures such as I have referred to. He will then follow certain well laid down lines, and when he comes to the end of the course he will be able to pass his final examination to his own satisfaction and to that of the Board of Examiners, and will go forth fully prepared to carry on his professional work. The public, in whose interest, I contend, this act was passed, will feel that they then have a man upon whom they can depend.

There is one thing that I think is more important than the tariff, and I hope the Government will take it into consideration. It is the removal of one word from that act of incorporation. When passing that act of incorporation, the Legislature put the word "registered" in front of the word "architect". We want that word erased, and just have it left simply architect. As it is now any person can practice the profession of an architect The inserting of that word has left the door so wide open that anybody can come in. Now, I may inform the members of the Government here to-night that there is a strong objection to this word "registered," and that the word "architect" is strong enough without being qualified in this way.

I have to thank you, gentlemen, for your kind attention.

After Mr. Berlinguet and Mr. Roy had made some further remarks on the tariff question, Mr. Lavasseur, of *L'Evenement*

CANADIAN ARCHITECT AND BUILDER.

VOL. VI.—NO. XI. NOVEMBER, 1893 PRICE 20 CENTS $2.00 PER YEAR.

—THE—

CANADIAN ARCHITECT AND BUILDER,

A Monthly Journal of Modern Constructive Methods.

(With a Weekly Intermediate Edition—The CANADIAN CONTRACT RECORD),

PUBLISHED ON THE THIRD THURSDAY IN EACH MONTH IN THE INTEREST OF

ARCHITECTS, CIVIL AND SANITARY ENGINEERS, PLUMBERS, DECORATORS, BUILDERS, CONTRACTORS, AND MANUFACTURERS OF AND DEALERS IN BUILDING MATERIALS AND APPLIANCES.

C. H. MORTIMER, Publisher,

Confederation Life Building, - TORONTO, CANADA.

Telephone 2362.

64 TEMPLE BUILDING, - MONTREAL.

Bell Telephone 2290.

SUBSCRIPTIONS.

The CANADIAN ARCHITECT AND BUILDER will be mailed to any address in Canada or the United States for $2.00 per year. The price to subscribers in foreign countries, is $2.50. Subscriptions are payable in advance. The paper will be discontinued at expiration of term paid for, if so stipulated by the subscriber; but where no such understanding exists, will be continued until instructions to discontinue are received and all arrearages paid.

ADVERTISEMENTS.

Prices for advertising sent promptly on application. Orders for advertising should reach the office of publication not later than the 15th day of the month, and changes of advertisements not later than the 5th day of the month.

EDITOR'S ANNOUNCEMENTS.

Contributions of technical value to the persons in whose interests this journal is published, are cordially invited. Subscribers are also requested to forward newspaper clippings or written items of interest from their respective localities.

The "Canadian Architect and Builder" is the official paper of the Architectural Associations of Ontario and Quebec.

Subscribers who may change their address should give prompt notice of same. In doing so, give both old and new address. Notify the publisher of any irregularity in delivery of paper.

ONTARIO ASSOCIATION OF ARCHITECTS.

OFFICERS FOR 1893.

PRESIDENT	D. B. DICK, Toronto.
1ST VICE-PRESIDENT	KING ARNOLDI, Ottawa.
2ND VICE-PRESIDENT	JOHN E. BELCHER, Peterboro'.
TREASURER	EDMUND BURKE, Toronto.

COUNCIL:

DAVID EWART	Ottawa.
S. G. CURRY	Toronto.
S. H. TOWNSEND	Toronto.
FRANK DARLING,	Toronto.
W. A. EDWARDS	Hamilton.

REGISTRAR AND LIBRARIAN:

W. A. LANGTON - Canada Life Building, Toronto.

MONS. H. LE CHATELIER, a French scientist, has recently succeeded in producing marble from pure calcined carbonate, This substance in the form of an impalpable powder, was enclosed in a steel cylinder and compressed between two steel pistons with a pressure of 1,000 kilogrammes per square centimeter. While in this condition, a platinum spiral previously embedded in the powder, was heated by an electric current, with the result that the powder in the neighborhood of the wire was rendered crystalline and translucent. Sections of the resulting substance when examined under the microscope exhibited the characteristics of certain specimens of slightly marled marble. This achievment though it may be useless from an economic point of view is none the less interesting.

THE storm which a few weeks ago passed over Ontario, and was the cause of great destruction of property, may be taken as an illustration of the fact previously adverted to that provision should be made by architects and builders in the erection of their buildings to resist the increased wind pressures to which apparently buildings in this country are likely to be subjected in the future. In the storm to which we have referred, the spire of a Toronto church was carried away, and the vibration of some of the buildings used for business purposes was so great as to cause serious alarm to the persons employed therein. There seems to have come a change in the climatic conditions of this country of which more violent wind storms are a feature, and their influence upon buildings should not be lost sight of by those who design them.

THE subject of the water supply of the city of Toronto has been one of general interest for many years past, more particularly during the last two years, within which a number of accidents have occurred to the waterworks plant, resulting in deterioration of the quality of the supply. The question as to what should be done to improve the supply and perfect the system, has been widely discussed, and numerous have been the theories advanced. The idea that water of much greater purity is obtainable at Lake Simcoe, and that it could be conveyed by gravitation to Toronto more cheaply than the necessary supply could be pumped from Lake Ontario by the existing method, is one which has apparently taken a firm hold on the minds of some of the citizens. The advocates of this idea argue that not only could water for drinking and other domestic purposes be supplied, of better quality and more cheaply, by this method, but also that power could be developed to operate all the manufacturing establishments of the city, as well as light the streets. These views were promulgated by one of the mayoralty candidates at the last municipal election. Whether or not the startling nature of the proposal had anything to do with his defeat, we have no means of knowing; certain it is, however, that the theory is not backed up by any engineering authority. The fact has been demonstrated that the water of Lake Simcoe is in no respect superior in quality to that of Lake Ontario. This is one of the important features in the case. Another is, that in the opinion of the City Engineer of Toronto, a tunnel can be constructed for half a million dollars which will ensure a supply of water sufficient for the needs of half a million people, while the means of bringing water from Lake Simcoe would cost millions. The height of land lying between Lake Simcoe and Toronto, would necessitate about twelve miles of tunnelling, the cost of which in itself would be enormous. As to the advantage of the scheme for power purposes, it is an undisputable fact that power can be produced cheaper by steam engines on the ground.

SIR David Macpherson in presenting his collection of palms and plants to the city of Toronto made, in referring to the Palm Garden of Frankfort on the Main, a suggestion as to the manner of housing them. A prominent merchant of the city, who has spent some months near Frankfort, has written to the *Mail* describing the Palm Garden in terms of enthusiasm and advocating the erection on the same model of a winter garden in Toronto. Sir David Macpherson's collection is evidently the nucleus of what may be made a very good thing. But it is well, in adopting ideas from successful features of European cities, to remember that such features can seldom be transplanted without modification. Continental modes of life are so different from ours that in appropriating ideas we must start from consideration of our own needs as carefully as in originating without a model; and it will usually be found, where the resulting work is good, that what was at first taken as an example has ended by being only a suggestion.

LORD ABERDEEN'S request for an addition to Rideau Hall has excited comments from the daily press varying according to the political bias of the paper. One paper is for leaving Rideau Hall as it is and forcing our Governor-Generals to conform their manner of living to the ideas of our farmers who, the leader writer asserts, are coming to the front in public affairs and will be found on the side of a policy of "democratic simplicity." Another paper is for pulling down Rideau Hall and replacing it by a "respectable looking mansion." It is, as it has turned out, a pity that this course was not adopted at first, for, according to the figures quoted, Rideau Hall, which cost $82,000 to purchase, has cost $53,000 for repairs and alterations. Whether the need of fifteen thousand dollars worth of more room is sufficient provocation to pull down what has been done and build the respectable looking mansion now, is a question. It would not be an exact response to the request of the Earl, who has not asked for a new mansion bye and bye, but for a few more rooms now. It hardly seems likely that the old Hall with its additions will be pulled down before it has had a life reasonably proportioned to the money which has been spent upon it. When the time does come for it to be replaced it is to be hoped that some steps will be taken to have the work well designed. It is not the class of building that is likely to be well handled by the Public Works Department. The forte of the Chief Architect's office is in its organization for the multiplication of buildings of a similar class An order for such an unprecedented and (unless the farmer forbids) elaborate piece of work as a new residence for the Governor-General would sweep the office like a cyclone. The pavilion representing Canada at the World's Fair has already proved too much for the elasticity of the departmental designer. If a new residence for the Governor-General should get into the hands which produced that work, it is impossible to avoid the conviction that however capacious the mansion might be it would not be "respectable looking."

THE by-law appointed by the City Council of Toronto some four years ago, making compulsory the inspection by the city officials of all plumbing and drainage work, as well as alterations in existing work done in the municipality, is unquestionably one of the most valuable pieces of civic legislation that has marked the history of the city. Previous to the passing of this by-law, the plumbing and drainage work throughout the city, even in the most expensive residences, was often done in a disgraceful manner, and in such a way as to prove injurious to the health of the occupants of the house. It was not unusual for drains to be laid without joints of any kind being made and in this condition covered up with earth and concrete, the character of the work being subsequently revealed when sickness entered the house. Under the present system, work of this kind is no longer possible; the owner or his architect can demand from those who are to do the work a certificate from the plumbing inspection department that everything has been done in accordance with the provisions of the plumbing by-law, and unless the work has been done in this manner, the department will not issue a certificate, and the owner may refuse payment. Another valuable feature of the by-law is, that plans for the plumbing and drainage work must be filed with the plumbing department, so that in the event of defects developing in the work in the future, the exact location the of pipes is ascertainable. A great deal of difficulty is often experienced in cases where alterations are required to work done previous to the passing of the by-law, as in such cases much trouble and expense is often necessary to discover the location of the drains. In this connection we wish to point out that greater care should be exercised in the plumbing department for the protection of the plans which are there filed, and the value of which we have already referred to. These plans are at present kept in pigeon holes in an ordinary wooden desk, where, should a fire occur, they would be certain to be destroyed. The plumbing department should lose no time in providing a fire proof receptacle for these plans, otherwise we may expect to hear that the valuable record of plumbing work done in the city for several years past has been irretrievably lost.

IN view of the hundreds of thousands of dollars that have been bequeathed to the engineering department of McGill University, it is a matter of wonder that not a dollar has been given for architectural education. Mr. Baillargé, in his paper read before the Province of Quebec Association of Architects, very truly says that there is a greater need in Canada to-day for instruction in architecture than in engineering. In engineering knowledge and ability Canada already takes front rank, and it is no doubt, partly due to the facilities which have been afforded for obtaining engineering knowledge. This knowledge is undoubedtly important, but cannot be said to be more so than a knowledge of architecture. Architecture, especially in the odern days in which we live, affects so closely the life andm happiness of the individual, that its importance cannot easily be overestimated, and in view of this, it is surprising that greater interest has not been manifested by the public in the proper education of architects. The range of knowledge required by the architect of to-day, is greater than that required by the engineer. He should to a large extent have the knowledge of the engineer, and in addition be conversant with the principles of sanitation, design, decoration, etc., of which the engineer needs to know nothing. On the knowledge of our architects depends the appearance of our towns and cities, as well as the comfort and health of the citizens, and a sense of pride, if nothing more should cause our people to assist in every way possible the cause of architectural education. While possibly little can be done for the architects of the present, steps should be taken to place within the reach of Canadian students of architecture in the future the means of acquiring the needed instruction pertaining to the successful practice of the profession. We trust that the Architectural Associations of Ontario and Quebec will continue to keep this subject before public notice, and that in the near future some of our wealthy citizens will feel it a privilege to give liberally for this worthy object. Unfortunately, architects themselves as a rule are not possessed of sufficient wealth to give much assistance to this object; were it otherwise, we have no doubt that facilities for the study of architecture would long ago have been provided.

OLD UPPER CANADA COLLEGE GROUNDS.

THE Parks and Gardens Committee of the Toronto City Council is considering a message from the Mayor proposing that the city should acquire the old Upper Canada College grounds "for park and other purposes." The price is the present assessed value of the land. The terms are so easy as to suggest the possibility of securing an open space and ornamental feature for the city with but little burden to ratepayers. It is possible so to lay out the land as to make building sites aggregating in value about the purchase price of the block, and still leave vacant enough land for ornamental open space. To do this will be a benefit to the city greater than the acquisition of the land for park purposes only. A park is after all an interruption in a city, while a square is a higher development of the city itself; and what is needed just now in that part of the city is development. Moreover, the removal of Government House, after some time, is probable; and its grounds are better fitted for park purposes than the grounds of Upper Canada College. They are better adapted to the purpose in form, but particularly by their southerly position. It is the southerly aspect that buildings require, and the Upper Canada College grounds with Government House to the south are a more eligible site for building upon than are the Government House grounds with a park on the Upper Canada College grounds to the north

Although it is possible to balance the cost of the whole block by the price of a portion only, laid out for building upon, it is of course impossible in the present state of affairs to do this at once, and so give the city an open space for nothing. Whether or not this may be the ultimate result is a question chiefly of population. But it is also a question of management. The value of the ground to the city, both as an attractive feature and also as a financial investment, depends to an extent that it would be hard to overestimate upon the skill and judgment with which it is laid out. It is a case for an expert adviser whose fee would be returned many times in increased availability of the land and its enhanced value. The better the opportunity given for profitable investment of capital, the greater is likely to be the response and—which is important—the quicker. There have been for some time rumors in the air of a big hotel, connected with the names not of one set of promoters only but of several. That the lack of such a hotel is a loss to the city is now common opinion. The Upper Canada College grounds have been often talked of as a suitable site. They are near—and yet not too near—the water, the Union Station, and the business part of the city. A site inside the grounds would give the hotel retirement from the streets combined with a southerly aspect and an outlook over the Government House grounds, which may some day form an even more pleasing prospect. If, by municipal intervention to treat the whole square, immediate surroundings which are agreeable can be secured for the hotel without involving an extensive purchase of land by its stockholders, it is likely that the scheme would at last hatch out and the big hotel form not only a speedy and large contributor to the cost of purchasing the block, but an attraction to other purchasers and a standard of character for the buildings, which would increase the revenue to be derived from the land and also raise the value of neighboring property.

TORONTO TECHNICAL SCHOOL.

LATE in the fall of 1891 the City Council passed a by-law establishing the Toronto Technical School, providing the means and appointing a Board, giving them full powers to obtain a building and equipment, to select a staff of teachers and to draw up a scheme whereby might be placed within the reach of mechanics and artisans and the employed of the city generally, the means of acquiring those elements of an education which would be of most value to them in the pursuit of their various avocations.

The preliminaries were attended to by the Board, but it was well on in January before the school could be opened. They had succeeded in securing for temporary use the building formerly occupied as Wycliffe College, on the north side of College street at the head of McCaul. It needed some refitting. From the start the school was well attended. The work of the first term was naturally to a great extent experimental, though by considering the special needs of the students and comparing the work done at various similar schools abroad, a programme was followed out which has not had to be materially altered excepting in the way of enlarging upon it and co-ordinating more thoroughly the different parts. This term extended to the first of May. Classes met five nights a week between eight and ten o'clock each night.

In October, 1892, the school re-opened, and again with a good attendance. This was expected to be the trying year. It was thought that the novelty of the appearance of this institution in Toronto might account for the good attendance during the opening term. If it tided over this year it would indicate that such a school could be of use. The register went up during the year to over three hundred and thirty, more than realizing the hopes of its most sanguine supporters. The school continued to thrive, though in cramped quarters, and with temporarily equipped class rooms. The students meant business, they came to learn; and the teaching staff worked with a will. The results were most satisfactory.

Again at the beginning of last month the school re-opened. The classes were crowded from the very start. As compared with a similar period last year the attendance this year has been multiplied by four. In the first week last year somewhat over 100 were registered; in the first week this year four hundred and fifty, and at the end of the second week five hundred and fifty were registered.

It is no longer a question whether there is room for such a school in Toronto. The experimental stage is past. It has come to stay. It is now for the city to show its appreciation of the value of such a school for the education of its mechanics and artisans by assisting it in its development, by providing it with more commodious quarters, and when necessary, by increase of staff or equipment. The sooner it is provided with better accommodations the better will be the results accomplished. It is now in a building greatly inadequate for the purpose. Why should not steps be taken at once to acquire for it better and permanent quarters? As long as it is cramped for room, and unable to separate the different grades and classes of work in the draughting room, as long as some of the elementary classes are three or four times their proper size, as long as chemistry, hydrostatics, light, heat, sound, electricity and electrical testing and laboratory work wait their turn in one small room, so long will the school be unable to accomplish the work that is evidently cut out for it in this city.

The ground at present covered by the course is comprised under the following heads: Mathematics (including arithmeti algebra, Euclid and trigonometry); Draughting (including practical, mechanical, architectural and geometrical drawing and copying, as well as classes in practical geometry, orthographic and oblique projection, perspective, etc.); Mechanics (including statics, kinematics and dynamics), Physics (including hydrostatics, heat, sound, light and electricity and magnetism); and chemistry (inorganic). There are two classes, a junior and a senior, in algebra, Euclid, mechanics, draughting and descriptive geometry, electricity and chemistry.

The students in chemistry also have the opportunity of doing practical work in a chemical laboratory which has lately been fitted up for the purpose.

While the course as outlined is as extensive as can be expected under the present conditions, there are still channels along which it might be still further developed—even while keeping along the same general lines—which would be of great benefit to a considerable number of students. Some of these extensions have already been proposed, but cannot be carried out for lack of accommodations. Classes in decorative design, freehand drawing, etc., have often been asked for. There are a number of subjects that would be of value to engineers and mechanics, such as the working principles of the steam engine, the testing of materials for strength, etc., foundry and machine shop principles, etc., etc. Other extensions would suggest themselves if the school were allowed to develop freely.

The Toronto Technical School has started well, and we hope to see it continue to prosper. We are satisfied that the city which has generously supplied it during its earlier days when its existence was an experiment, will not now allow it to stop short of its full possibilities.

ILLUSTRATIONS.

RESIDENCE FOR C. W. LEONARD, QUEEN'S AVENUE, LONDON, ONT.—MOORE & HENRY, ARCHITECTS.

This building consists of basement, two main floors, and finished attic, and is built facing the south. The foundation is of Credit Valley brown stone, and the upper walls of red pressed bricks and red sandstone.

The interior is finished in various hardwoods, heated by hot water and lighted by gas and electricity; cost $12,000.

ENTRANCE TO FREEHOLD LOAN BUILDING, TORONTO.—E. J. LENNOX, ARCHITECT.—HOLBROOK & MOLLINGTON, SCULPTORS.

WESTMINSTER PRESBYTERIAN CHURCH, TORONTO.—GREGG & GREGG, ARCHITECTS.

QUESTIONS AND ANSWERS.

[Readers are invited to ask through this department for any information which they may require connected with the objects of the paper. Every effort will be made to furnish satisfactory answers to all such inquiries. Readers are requested to supply information which would assist us in our replies. The names and addresses of correspondents must accompany their communications, but not necessarily for publication.]

E. A., Toronto, writes: Through the columns of your valuable paper would you please tell me what extra training would a person holding a School of Practical Science Diploma of Architecture require to become an architect?

ANSWER.—We presume that by "an architect" E. A. means a member of the Ontario Association of Architects. A graduate of the School of Practical Science can become a member of the Association by serving under articles of apprenticeship, in the office of a member of the Association for three years (of which one year may have been served during the vacation of the School) and by passing the examinations of the Associations.

SPURIOUS HARDWARE.

SOME of the leading hardware merchants of Toronto complain that duplicates of some of the more favored and expensive patterns in American hardware are being manufactured in cast iron in Toronto, and after being plated are placed on the Canadian market, represented to be the genuine article. At first appearance the spurious goods are a good copy of the genuine and can be detected only by very careful examination. To make detection still more difficult, a genuine lock is often used with a counterfeit escutcheon. A close inspection will usually reveal that the counterfeit article, while perhaps identical in color, is slightly smaller in size than the genuine. This is due to shrinkage in casting, in the process of which one of the genuine articles is used as a pattern. The genuine article is made of bronze metal, which to a considerable extent is impervious to the action of the atmosphere. The imitation is as we have said made of cast iron, and will retain its appearance at the longest only a few months. The importers of expensive American hardware claim that they should not be placed in competition with a spurious article which can be produced at a tithe of the cost of the genuine. If architects are satisfied with cheap goods they are quite willing to compete on that line, but they should not be excepted to place a genuine article in competition with one to which the same name and appearance have been given, but which is counterfeit. Architects would do well te enquire into this matter.

THE RE-INFORCEMENT OF CONCRETE BEAMS BY TWISTED IRON FOR FIRE-PROOF FLOORS.

The reference made in the May number of the *California Architect* to the use of twisted iron incorporated in concrete, has called out some inquiries, says that journal, as to the nature and extent of the tests so far applied to this mode of construction. Though first introduced upon this coast but little has been published here respecting this new departure in fire-proof building.

The Museum at the Standard University was not the first structure where this method was employed, but the concrete beams supporting the heavy dome, have the longest span yet produced, forty-five feet. Another notable example is the California Academy of Sciences on Market street, where five floors covering an area of 50,000 square feet are so constructed. The span ranges as high as thirty feet, and there is also a projection of three feet of concrete over the central area, supporting an iron railing at the outer edge, and walk for visitors. The floors were estimated to carry with safety 250 pounds per square foot. One section, 15x22, was tested with a uniform load of 415 pounds per square feet, and the load was left on one month. The architects reported the extreme deflection at the center as only one-eighth of an inch. Contractors and workmen were distrustful at first, but their confidence became unbounded before the completion of the work. The saving over the usual mode is estimated at fifty cents per square foot.

Touching the weight of these floors, as compared with iron girders and hollow tiles, the first impression that the concrete must necessarily be much heavier, is found incorrect. For when the span is of usual length, and the required strength of moderate limit, the weight per square foot is less with the new construction. For example: with spans of fifteen to twenty feet, and a safe load of seventy-five pounds per square foot, the saving in weight is about forty per cent over iron girders and hollow tiles. With a load of 129 pounds it is some twenty per cent.

This economy is doubtless due to the fact that the bond between the twisting iron and the enveloping concrete is so perfect and continuous as to give the effect of a homeogenous beam, and that the tensile strength of the iron bar is utilized.

Ordinarily in the use of iron with concrete, the strain has been concentrated at a single point by the employment of nuts and washers. By twisting the iron before it is imbedded in the concrete the strain is diffused equally through the length of the bar while it is firmly held at all points by the enveloping mass.

An incidental advantage of the twisting is that thereby all imperfectly laminated iron is at once detected, and the defect exposed, ensuring the employment in practical use of only a high quality of iron.

In the more common forms of construction the major element has been the iron beam, whose lower cord was exposed, necessitating additional protection below against the action of heat. By substituting the concrete beam as the chief factor, the iron used is so incorporated within the body of the stone as to be amply protected without extra cost. Moreover the iron girder is an expensive form, while the very simplest or cheapest is the flat or square bar.

The claim that cold twisting actually adds to the strength of the bar, rests upon somewhat exhaustive experiments conducted by Lieutenant F. P. Gilmore, U. S. N. (Government Inspector of Iron and Steel for war vessels under construction at San Francisco) and by the College of Mechanics of the University of California at Berkely, also at the celebrated Low Moor Iron Works, England.

Lieutenant Gilmore found that common commercial iron ¼ inch square, being given 1½ twists per lineal foot gained seventeen per cent. in tensile strength; given 3¾ twists, twenty per cent., and six twists gained twenty-four per cent.

The best Norway Iron given six twists per foot, gained from fifty to fifty-three per cent in tensile strength.

Similar experiments at the Low Moor Iron Works ¾ inch round iron, showed twenty-two per cent gain for 1½ twists per foot; thirty-six per cent. with 2½, and forty-one with three twists, which were as far as the experiments noted were carried.

The latter experiments conducted by the University of California gave similar results, with one important fact ascertained, namely: that a suitable interval between the twisting and the testing gave a much greater gain. Three-quarter inch iron turned down to ⅝ was given six twists per lineal foot. Twisted while hot there was a small loss in tensile strength. Twisted cold and tested immediately, the gain ranged from twenty-three to forty-three per cent. Twisted cold and allowed to remain five days and then tested, the increase in tensile strength of the same quality of iron was from forty-seven to fifty-nine per cent. or an average of fifty-three per cent.

It would seem that advantage might be taken of this important augmentation of tensile strength in many places. Bridge builders, as well as workers in concrete, would do well to inform themselves fully upon this claim.

"CANADIAN ARCHITECT AND BUILDER" COMPETITION.

The publisher of the CANADIAN ARCHITECT AND BUILDER invites competitive designs for a town house and stable to cost not more than $4,500.

The house is to be placed on the east side of the street. The lot is 35 feet wide and 125 feet deep. The houses on either side are built up to within three feet of the dividing line, and are fifteen feet from the street line.

The stable should provide accommodation for one horse and accoutrements, and vehicles for summer and winter use. Access to the stable can only be had from the front of the lot.

The house is to be heated with hot water. Arrangement of piping, location of radiators, etc., should be indicated.

Good planning from the standpoint of health, convenience and comfort, will be given first consideration in judging the designs.

Each competitor must give a concise description of his design, stating the materials proposed to be used in its construction.

Drawings must include two principal elevations, floor plans and detail of hall and stair. A perspective may be submitted at the option of the competitor.

The first premium will be $15.00; the second $5.00; the third, one year's subscription to the CANADIAN ARCHITECT AND BUILDER.

Drawings must be made on sheets of heavy white paper or bristol board 14×20 inches in size, and must be drawn sufficiently coarse to allow of their being reduced to one-half the above size. Drawings must be made in *firm strong lines*, with *pen* and *black ink*. *No color or brush work will be allowed.* Each drawing must be marked with the *nom de plume* of its author, and the author's name, *nom de plume* and full address, enclosed in a sealed envelope, must accompany each drawing sent in.

Drawings must reach the office of the CANADIAN ARCHITECT AND BUILDER, 107 Confederation Life Building, Toronto, not later than the 2nd day of January, 1894.

The right is reserved of publishing any design sent in. All designs will be returned to their authors within a reasonable time after the competition is decided.

The decision as to the respective merits of the designs submitted will be made by a committee appointed by the Architectural Guild of Toronto.

All architects practising in cities are debarred from this competition.

MONTREAL.

(Correspondence of the CANADIAN ARCHITECT AND BUILDER.

Last month I quoted from a letter of Mr. L. J. A. Papineau, in which he expressed his regret that so little veneration is shown in this country for ancient buildings. That this disregard for ancient historic landmarks is not universal is however very clearly snown by the interest lately exhibited by all classes of our citizens in the preservation of the old Chateau de Ramezay on Notre Dame street opposite the City Hall. When it became known that it was the intention of the Quebec Government who were the owners of the property to offer it for sale at auction, the Numismatic and Antiquarian Society immediately set about means to prevent the sacrifice of the old building which is one of the few surviving links binding the early history of the city with the present. Meetings were held and resolutions passed asking the City Council to purchase the property with a view to the restoration of the building as a public library and historical museum. Several valuable gifts of books, historical pictures and other relics were promised in case the property was preserved. Petitions were also placed in circulation and signed by upwards of one thousand leading citizens praying the Council to purchase the property. As a result of the general interest thus manifested, the Council at a special meeting called to consider the subject, consented to the petition, and at the sale which took place on the 23rd of Oct., the Mayor on behalf of the city purchased the historical Chateau for $27,000 and some of the adjoining lots for $18,506, while several members of the Antiquarian Society, with the object of preserving to the city the whole square, and preventing the appearance of the old Chateau from being spoiled by objectionable architecture, bought the corner with the three adjoining lots. The property thus purchased at a cost of $32,396 is now offered to the city at cost price.

A movement is on foot with the object of providing a residence in this city for the Governor-General, and the Council are to be asked to consider an offer of Mr. Duncan McIntyre's mansion on Drummond street at the price of $300,000 for this purpose. In view of the enormous expenditures for public improvements in this city of late, and the heavy interest charges which in consequence must be borne, the wisdom of a large outlay for this purpose may very properly be questioned. In connection with Mr. McIntyre's house an interesting suit is now pending in the courts. The widow of the late W. T. Thomas, who was the architect of the building, has brought action against Mr. McIntyre to recover some $35,000, alleged to have been earned by her husband in connection with the erection of the building. The larger portion of the sum mentioned represented 10 per cent. commission on the alleged cost of the house. The owner of the house denies that he agreed to pay a commission on the cost. The court upholds him in his refusal to state what the cost was. The matter has not yet reached decision.

J. NELSON, A.R.C.A.,
President Province of Quebec Association of Architects.

The right of the proprietor of a building which is under lease to make changes therein is involved in a suit brought against the Royal Insurance Co. of this city by a firm of advocates occupying offices in their building. Plaintiffs claim that damage was caused to their practice by the changing of the motor power of an elevator, which was hydraulic, to electric power. Defendants contended that a proprietor has a right to make changes in the premises occupied by the tenant, provident due diligence be exercised. Plaintiffs argued that due diligence was not used, and that in any case the proprietor cannot make alterations or changes in the premises. The case is yet undecided.

The Royal Victoria hospital is shortly to be opened by Lord and Lady Aberdeen. A description of the building has already appeared in the CANADIAN ARCHITECT AND BUILDER.

I have much pleasure in forwarding to you for reproduction in the ARCHITECT AND BUILDER a portrait of Mr. J. Nelson, AR.C.A., the newly elected President of the Quebec Association of Architects. Mr. Nelson has been a modest, though valued worker in the interest of the Association since its inception, and the honor which has been conferred upon him could certainly not have been more worthily bestowed.

The Victoria railway bridge over the St. Lawrence at Montreal contains 3,000,000 cubic feet of masonry work and 10,500 tons of iron.

LONDON.

(Correspondence of the CANADIAN ARCHITECT AND BUILDER.)

The building season of 1893, owing to the exceptionally fine weather with which we have been favored, will be longer than usual. In this city at least the season which is about to close has been the most active in building enterprise experienced for a number of years. So far as I can learn none of the local architects have had occasion to complain of lack of work, while some have found it necessary to trespass on the hours which ordinarily are devoted to other purposes.

In many of the new buildings erected of late there is pleasingly manifest a striving on the part of our architects after the artistic and aesthetic in the treatment of their designs, a disposition to depart from old time sterotyped ideas, which is deserving of commendation. In most instances the efforts made in this direction have had a beneficial effect upon the architecture of the city.

HAMILTON.

(Correspondence of the CANADIAN ARCHITECT AND BUILDER.)

The past season is declared by local architects to have been one of the most active in building enterprises experienced here for several years, and there are a number of new buildings projected, which it is believed will make the season of 1894 a busy one also.

Some expensive residences are at present in course of erection. Among these are the residences of Mr. George T. Tuckett and Mr. C. M. Counsell, both designed by Mr. James Balfour, architect, of this city. Mr. Tuckett's residence is nearing completion, and will be occupied by the owner in a few weeks. It ranks among the most expensive residences of the city, and is certainly one of the most modern in its interior arrangements. It occupies a site on rising ground, and affords a pleasing view of the Bay and Burlington Beach in the distance. The building throughout is constructed in the best possible manner, and with the best materials. There is no attempt at elaborate ornamentation, but utility, comfort and good taste, are everywhere apparent. The joinery work, which is being done by Messrs. Jos. Hoodless & Son, is deserving of all praise. For interior finishing, oak, bird's eye maple and mahogany, are principally employed. The brick and stone work was done by Mr. Geo. Webb; the plumbing by Messrs. Fairley & Stewart. The heating will be done by two Daisy boilers of the largest size, arranged so that one or both may be in operation as may be required. The drawing room will be decorated in white enamel with white silk panels, the mantel of white onyx. The ceiling will be decorated in keeping with the rest of the room by Messrs. Elliott & Son, of Toronto.

Mr. Counsell's house, although much less expensive, occupies a pleasing location at the corner of James and Markland streets, and exhibits many original and pleasing features of design. The lower story is constructed of stone and the upper stories of brick and wood. The stone was obtained from a local quarry, and is of good quality but very hard, and so brittle that it is apt to split under the workman's chisel. Often a block will give way just when the work upon it is about finished, thus proving an expensive loss. To such an extent has this occurred that the contractors' profits are not likely to be very substantial. The house is roomy, carefully planned, and excellently lighted, and will no doubt afford every comfort to its owner.

On October 23rd, at the Church of Our Lady of the Holy Rosary, Thorold, Mr. James Battle, cement manufacturer, was united in marriage to Miss Mary Conlon.

At Ingersoll, Ont., a company has been formed and acquired the Canadian business of the Guelick Silica Barytic Co. of Detroit. Mr. Walter Mills, who was manager of the Canadian business of the Detroit Co., will continue with the concern.

An anonymous correspondent of the Orillia *Times* recently declared that "local contractors hesitate to submit tenders for work designed by Mr. W. H. Crocker, architect, of that town; being doubtful whether honest competition would prevail." Mr. Crocker, through his solicitor, has demanded a retraction over the signature of the writer. It is to be hoped that the person who would make such a serious imputation under cover of an assumed name, may be compelled to disclose his identity.

AMERICAN SCHOOL BUILDINGS.*

As to the requirements of a sanitary school building and one best suited to the needs of children, say a common school of twenty rooms: First, it should be as nearly fire-proof as practicable. Children do not have the strength and experience of adults and cannot look out for themselves. If it cannot be fire-proof reduce the fire risk as much as possible. Wooden partitions, though often used, should be avoided. If outer walls are furred, it should be done with fireproof furring. Stairs should be enclosed in brick shafts, and the stairs themselves made of solid material, preferably of hard wood for both risers and treads, with fireproof or slow-burning construction underneath them. If floors are of wood on wooden joists, as they generally must be, the spaces between the joists should be cut off with solid plank in addition to the usual bridging. On no account should the floors be raised from the joists for the purpose of circulating air underneath unless all parts are fire proof. Floors should be of good smooth hard wood, closely laid on an under floor, and deadened with mineral wool or something as good. Joists should not run through from wall to wall, and should be so placed as to drop out without tearing the wall in case of fire. The danger from fire can be considerably lessened by judicious planning, so that all rooms are easily accessible to the halls and the stairs. All exits should be so plainly indicated that a stranger would have no trouble in choosing them at once.

The sanitary school building should be well lighted. This matter has received considerable attention from scientific men. It is claimed that an ideal system would bring in the light from the top of the room and distribute it equally throughout. Many object to this because it appears prison-like; besides in a building with one room over another it is impracticable. School-rooms being generally lighted from side windows it becomes a question as to number and location. It is conceded that the light should enter as near the ceiling as possible, therefore windows reach to the ceiling or nearly so.

It has been customary to follow the rule that light should come over the left shoulder, so as to avoid a shadow on the desk from the right hand; but while this is a good rule it is found hard to apply it where several pupils are together, as in a school-room, since that which will be left-shoulder light for one pupil will not be for some other. In practice an average is struck, and the windows so placed as to properly accommodate the greatest number. With windows on one side only about one-half the pupils get the left-shoulder light in some degree when they sit with the left side to the windows. The other half get the light chiefly in the left eye, or more in the left than in the right. That is a bad arrangement and prolific of unequal vision. This can in some degree be lessened by placing the side windows well towards the rear, and placing some on the rear as well. There is then, however, the objection that the pupils in the diagonal corner furthest from the light are too much in the dark.

In a room lighted wholly from one side and the pupils placed with back to the light some curious facts are noticeable. First, the same number of pupils receive left-shoulder light, as in the former case—that is, one-half; the other half receives the light over the right shoulder, not a desirable thing and not to be tolerated unless there is enough reflected light to dissipate the shadow cast by the right hand on the desk. If there can be such reflected light, and there is no doubt about that, it gives the best light I know of for so many pupils, since as many get left-shoulder light as in the other way, and none of them get it partly in front. That this is the best arrangement for pupils I think there can be no question, though upon the teacher it is especially hard, though it may be said that the teacher can always move about, while the pupils must stay where they are.

I think it is common to put some windows on the side and some on the end of each room, where it can be done, though I am inclined to think the side light the better, if it could be properly curtained and managed by the teacher. Whatever the position of windows there should be plenty of them.

The sanitary school building must be well heated and ventilated. These two things can be considered together, though heating alone used to be the first and only consideration. The requirements call for the right amount of fresh air and heat, properly introduced to the rooms and circulated therein. Economy seems to call for a central plant for the supply. One of the main difficulties to overcome after a good heating device has been provided is the proper inlet, exit and circulation of the ventilating air in the schoolroom. Unless this work is properly done the whole plant is a failure, and it is a fact that much confusion exists as to the method to be employed. The problem is made more difficult of solution because the atmospheric changes are so rapid and radical that no single arrangement of the working parts will answer for any certain time. Obviously the best way to have the air enter a schoolroom would be at openings all over the floor, and it should leave at a like number of openings in the ceiling. That way is not practicable where rooms are over one another, and therefore the common way of introducing air into the room is by single and ample opening. It is let out by another. Where these inlets and outlets shall be placed with reference to each other and the room itself is a question in dispute. Much confusion obtains on this point—perhaps because people believe it is possible to adjust the openings to suit all occasions. The question will be much nearer solution when this belief is eradicated. In some rooms the inlet will be found at the top and the outlet at the bottom; in others it will be the reverse. In some there will be inlets and outlets at both top and bottom; in others the inlet and outlet on the same side of the room. In others the inlet will be on one side and the outlet on the other.

Probably there will be confusion on this point so long as the single inlets and outlets are used.

We must have circulation through the room and we get it in one of two ways. Either the air may enter cooler than the room, in which case, if the inlet is at the bottom and the outlet at the top, a fair circulation will be given; or the air may enter warmer than the room, when, if the inlet is at the top and the outlet at the bottom a good circulation will be got.

Since it is a fact that air must sometimes enter warm and sometimes cool, so as to maintain the standard of heat, it will be seen that neither arrangement of openings will answer for both cases, and the working parts cannot be so fixed as to give perfect satisfaction. If both inlets and outlets are provided at top and bottom when cool air is wanted, the floor inlet and the ceiling outlet can be used. When warm air is wanted the ceiling inlet and floor outlet can be used. But aside from the difficulty of getting any one to understand it, it would take one person's time to watch the thermometers and manage the dampers. Present practice largely adopts the ceiling inlet and floor outlet, ignoring the fact that incoming cool air falls to the floor, and poor circulation is the result.

This intermittent lack of circulation is a grave difficulty and hard or impossible to be avoided when the inlet is high and the outlet low, more especially when a room is heated by air alone.

Some engineers try to prevent notice being taken of the difficulty by putting the inlet at or near the floor. When the air comes in warm it rises to the ceiling, distributes, cools and falls to the floor, leaving at the foul-air opening. Under these conditions the air appears to circulate properly, the only objection being a current of hot air striking the pupils. The current of air is made less noticeable by a screen; that is, of course, unnecessary when the inlet is above. On the other hand, with inlet at the floor and the air coming in cool, there is and can be little or no circulation through the room, the air simply entering, flowing along the floor, and leaving at the outlet. This seems to be a case of out of sight and notice, out of mind. The lack of ventilation is not easily discovered, and thus gives a fine chance for the professional quack to show off his system of ventilation, for with his air meter at the inlet and outlet he finds the full volume of air passing that he guaranteed to furnish, and no one stops to inquire whether that air gets to the proper parts of the room by circulation.

I believe it would be a good system to heat the floors evenly and always bring the air in cool, provided that the floor heat could be controlled and unpleasant draughts prevented.

It is hard to say where the inlets and outlets should be placed to satisfy all conditions, but I have advocated putting the inlet high and the outlet low, though I am quite ready to change should a better way be found.

The general plant that is to furnish the heat and ventilation in a sanitary school building must be ample to do its work. It must be durable, cheap to put in, and cheap to maintain. Furnaces furnishing hot air, steam plants and hot water plants, with numerous modifications and partial unions, are the principal kinds used in school buildings. For years the furnace did good duty, and it still holds its place, at least in the smaller class of buildings. Its first office was probably that of heating, though it was made so that it had to furnish ventilation in order to heat. When steam first came into use its work was entirely that of heating, and for a time schools heated by steam were a long way behind those heated by furnaces. Necessity soon compelled the use of indirect radiators to heat air for ventilation. This system had quite a run, and is still used, though it gradually loses favor as better methods come up.

The marked advance in ventilation during the last few years has been the adoption of a fan or fans run by power for sending the air to the rooms. In furnace-heated buildings the only methods of creating suitable currents was by heat and in order to induce currents in the foul air shaft it was connected with the smoke stack the heat of which caused the current. In steam-buildings coils were used in addition to the smoke stack. It has recently been discovered, however, that the heat used to create currents, in the foul-air shaft would be of more service in running a fan to do the same work. Hence fans are in common use. There is a difference of opinion whether one fan or two shall be used. I am of the opinion that with our ordinary leaky rooms two do the work better than one, though there is room for argument on that point.

From the old form of steam plant have sprung many modifications. There is one that heats entirely by steam coils placed in a fresh-air room in the basement, the air being blown to the rooms by a fan. At present I favour the adoption of a central steam plant, running direct radiators to the rooms, an indirect set of radiators to heat the fresh air, a fan to blow it into the rooms and an exhaust fan to take it out. In a cold climate it works well; in fact, I do not see how it would be possible to get so good results from any other method. In warmer places than Minnesota I suppose the hot air system would be sufficient.

This steam system has its faults and can be much improved, especially as regards details of arrangement. While being somewhat more costly to put in than the indirect method, it makes a very low record for fuel, a good point in any plant. Contrary to expectation, it has been found cheaper to run and fully ventilate than to run the old steam plant without ventilation. It was said when fans came into use and talk of 1,200 cubic feet of fresh air per hour per pupil was made, that it might be very well and quite necessary that we have this fan ventilation, no matter what it cost for fuel. That the fuel bill would be increased no one doubted; nevertheless, it has decreased, and this fact should be a strong argument for its adoption over the country.

The sanitary school building should properly dispose of its waste. I declare for first-class plumbing, without hesitation, where sewerage connection can be had. Where it cannot be had and cesspools are impracticable, I am not so certain what to say. There is a choice between dry closets, crematories and out-of-door privies. As to plumbing, it has been often and justly condemned. It has been the cause of much sickness and death. Whatever it has been, the day has come when a plumbing job can be made practically perfect so that it can be fully recommended for any kind of building. In our modern school building nothing can be better than our best known water-closets, with slate or glass urinals.

However, there are schools where plumbing cannot well be had. There seems to be demand that all toilet rooms shall be inside the building. This demand I believe to be just, provided the inside toilet room can be made quite sanitary; the demand ought to be complied with. But here is the difficulty. The problem seems nearer solution than it did years ago, but there has been great injustice done in the attempt to get a safe device. The principle of the dry closet and crematory is either to dry or burn the sewage. There has been a dry closet in use more or less where the privy vaults were in the basement but wholly unconnected with any other part of the building. This seems to have met with fair success, at least in that it does not admit odors to the schoolrooms, but it costs a large amount for fuel and has no great run.

There is another dry closet in which the privy vaults are connected with the schoolrooms by means of hollow wooden floors and partitions, though sometimes this connection is made through direct ducts. This bold step was evidently taken to save fuel, and though the whole device was carefully arranged and it possesses many taking points, I believe it is inevitably doomed to condemnation as an unsanitary device. No privy vaults connected directly or indirectly with the schoolrooms ought to be upheld for a moment, for although the draught may be made to go the right way some of the time, it will occasionally back up from the privies into the rooms, and no such thing should be tolerated. If outside privies could not be used it would be better for a scavenger to stand at the basement door with a cart and remove the contents of vaults daily or hourly, than for the public to tolerate such a thing. Happily there is a strong sentiment against this device, and attention is being wisely turned to more sanitary contrivances.

Along this line it may be well to say that the recent crematory closet seems to be somewhat in advance of the old dry closet. It has at least the merit of not being connected with the rooms, so what odor there is, not going up the stack provided for it, is not likely to get into the rooms. I have not seen the crematory closet tried, but it seems to promise well. The only difficulty I can foresee is the disposal of the urine, which will accumulate in unpleasant quantities unless the greatest care is taken.

COMBINATION LEAD AND FELT ROOFS.

A novel style of roof combination which is likely to prove more or less interesting to American readers, has been brought to the attention of the foreign world by an invention of Herr Siebel of Dusseldorf, the history of which is decidedly entertaining. The inventor was well aware no doubt that the best protection against dampness arising from the ground into walls is a sheet of lead, and that on account of the great expense of a protection of this kind of sufficient thickness to support the weight of superstructure without tearing, it is common in these days to substitute a sheet of tarred felt. Bearing these things in mind he conceived the idea that both materials might be employed to advantage by inclosing a thin sheet of lead between two thicknesses of tarred leather.

In this way the metal, although thin, acts as an impenetrable barrier to dampness and is not liable, as is the case with felt when used alone, to gradual decay. While engaged in perfecting his invention it occurred to Herr Siebel that the felted lead would make an impervious roof covering, and perhaps a durable one, and thorough tests seem to confirm this idea. The felted lead is solid in the same form as ordinary roofing felt, and applied in the same manner, receiving the usual protecting coating of tar and gravel on top; but the metal protects the felt under it so completely from the evaporation of the volatile portions of the tar, which is the principal cause of the deterioration of composition roofs, that it is said to remain tight for an indefinite period. Even when the lead is exposed, from the decay of the felt over it, nothing is necessary but to lay over it new felt, with tar and gravel finish, to make the roof as good as ever, while an ordinary felt roof which has once begun to rot is not usually worth repairing. The practical man will think of other details, such as the facility with which flashings, gutters and zinc or copper edgings can be soldered to the lead of the roofing, which seems very much in favor of the new material. It is, however, difficult to rool very thin lead, and it is hard to understand how sheets enclosed in felt could be sold for roofing at a price to compete with a tin roof, which would be better in most respects.

PERSONAL.

We regret to learn that on the 21st of October the residence and office of Mr. James A. Macdonald, architect, Regina, N. W. T., with their entire contents, were destroyed by fire. Mr. Macdonald's instruments, papers, and library were among the articles destroyed.

TRADE NOTES.

Sheathing "Quilt" is the name of an article recently patented by Samuel Cabot, of Boston. It is intended to take the place of back plastering and other expensive methods now in use for deadening sound and making dwellings and other buildings temperature proof. It owes its name to the fact that it is made of a tough saline grass held in place between two layers of manilla paper by quilting. Its great elasticity makes it a remarkable sound deadener, and its use in this way is quite as great an economy as in any other.

* Abstract of paper read by Walter S. Pardee at the annual convention of Building Inspectors and Commissioners at St. Louis.

A TABLE FOR TREADS AND RISERS.

FROM *The California Architect* we republish the following table, which will be found very useful to many of our readers. The spacing of the lines of figures into groups aids the eye in following the direction to the final point.

DIRECTIONS.—In the column beginning with the rise of step desired, find the height of story from top of floor to top of floor, then follow this line to the column under "Risers," which gives the number of risers. In the column under "Treads" find the number of risers *less one*, and on this line under the column of width of tread will be the length of run.

Risers	inches	Treads	inches	inches	inches	inches	inches	inches	inches	inches	inches	inches	inches	inches	inches

METHOD OF STORING MOULDINGS.

Mr. Owen B. Maginnis writes as follows on this subject in *The Woodworker*:—

Concerning the proper storing and safe keeping of strips and moldings, I think the most convenient way to place them for convenient use is that shown in Fig. 1. A rack or series of holes or spaces is made, by framing together a front out of 1¼-inch or 1½-inch stuff (pine is good enough) after the manner of Fig 1, which is shown to be 10 feet 6 inches high. The

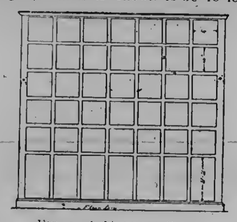

FIG. 1—A MOLDING RACK.

SECTION.

bottom space is 2 feet two inches high and 14 inches wide. The case is ten feet wide, so that 7 spaces are obtained. The bottom spaces are made thus for the larger sizes of moldings or strips, so that they may contain more, and rest solidly and safely on the floor.

In every molding rack the heavy stuff should be stored below, and in order to get a larger quantity into a given space it will be necessary to make the space large.

The rack illustrated here contains 42 spaces for moldings of different sizes, and for convenience and readiness of handling the smallest moldings, as ⅝ and ¾, beads, quarter-rounds, cones, and such like, are placed in the upper spaces. The section drawn to the right will give the reader a fair idea of its construction. The sides can either be left bare or covered over with ⅞-inch matched stuff, and a crown mold broken round the top to give it a finish, as shown.

The practical mill man and wood worker will at once perceive the convenience of a storage rack like this, for the reason that 42 different sizes and designs of mouldings are a good many, but if more be carried in stock a larger rack with more spaces can be made, or another section added to the one already made. In addition to this, the quantities in stock can be quickly computed, especially if the rack be made a fixed length—say 11 or 15 feet; then 12 and 16 feet lengths can be stored in it and the accurate number of lineal feet arrived at by counting the ends in each space. I am a great stickler for order in a mill, and would

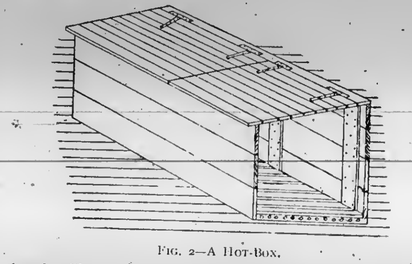

FIG. 2—A HOT-BOX.

therefore like to see one of these conveniences in every well-regulated one. Numbers can be affixed to the face of the frames for catalogueing and ordering. The dimensions of the various pieces I have marked on the sketch, so that anyone who wants to make a rack after this pattern can easily do so.

At Fig. 2 will be seen an isometrical drawing of a hot box for heating stuff preparatory to glueing. The pieces can be handily placed in it, being laid on the strips on the bottom, which lie on the steam pipes underneath. The box can be constructed of ⅞ or one-inch matched or tongued and grooved boards, not wider than six inches, being held together by battens screwed on in the way shown in the interior. The lid is hinged by strong common T-hinges and may, for extra convenience, be in two halves or flaps, in order not to let the heat escape by exposing the entire inside of the box.

DECORATION AND FURNITURE

MANUFACTURED AND REAL ART.

We have heard a good deal about artistic craftmanship, as if it was our duty to invent certain trades for the benefit and pleasure of artists; without for one moment believing that art may be found in every trade, if it be only honestly exercised, and the materials honestly used. For at least 40 years we have been encouraging what we may term "manufactured art," or importing some foreign style; trying to make our furniture, our fabrics and textiles, our metal work, and other things "artistic," to impart to them certain plastic qualities of form and grace and of harmonious colour without seeing or even suspecting that all this effort is thrown away; that, in fact, we cannot force our "art" notions on things or on materials, but that whatever good or beauty and grace an article possesses must be a spontaneous growth out of the material and condition of workmanship. Cultivated people are beginning to turn with well merited disgust from so-called "revivals" and "art" furniture, "æsthetic" carpets and fabrics, "mediæval" brasswork "Queen Anne" or "Jacobean" sideboards and cabinets, chairs and tables, "Japanese" ware, "Empire" decorations, and a variety of other prefixed adjectives of this sort; they begin to see that there is nothing honest about a kind of manufacture which has no claims to be called either Queen Anne or Empire, or by any other title except that it has been made to imitate work of those periods—descriptive titles that have only a meaning in the catalogues of Wardour street or Tottenham Court road.

When will the people learn that we must clothe modern ideas in modern dress? When will they see the absurdity of slavishly imitating old furniture, woodwork, or copying old Persian tiles or the "Book of Kells" for needlework and embroidery? The same desire to make our new work like the old is observed in the copying of old plaster or stone relief in modern compositions for wall and ceilings, or oak carvings in materials which they have no affinity for, to sympathy with, whatever. We have nature open to us as well as the ancients had; we have our own materials to work with, our own requirements, as well as they had. Why do we not make the same use of them as our ancestors? The question awaits an answer. Contrast for a moment the woodwork or furniture on the 16th or 17th centuries with a piece of vulgarised shop work. In the former we observe conversion of the material which was used with meaning and intention; the ornament was an interpretation of nature in sympathy with the material, whether wood or plaster. The workman *started* with an *idea*, instead of borrowing one from some ancient source; his *motif* was derived from his own conception. For practical examples of the contrast, let us compare the woodwork of some old hall in Cheshire or Warwickshire, or a 17th century cabinet at the South Kensington Museum, with a piece of modern workmanship of the Tottenham Court road class, and we at once perceive the differences. In the former there is no meaningless repetition in the modes of framing or ornamentation.

We must look to the practical working of the trades for improvement. If a material or a piece of workmanship is susceptible of art, it can only exhibit it by a close observance of its peculiarities, or by the method employed in converting it. Practical design as it is taught in our art schools consists merely in making designs on paper according to certain conditions, whereas it can only be developed by a close study of the material. Take, for instance, carpet design. The success of the pattern depends on the designer's knowledge of the fabric. How many tints must be used to produce a gradation of colour?—as every patch of colour pattern must be defined in the and be thought of like the tessere of a mosaic. It also depends on the number of colours, the "planting" or dividing the bands of colour or frames, to produce a given design, and the repeats. The designer may make a beautiful arrangement of pattern and colour; but if it does not fulfil the technical conditions it is useless. For these reasons it is better to encourage the working out of those designs which can be most naturally effected, to avoid any complicated and strained efforts, and mainly that the limitations or restrictions imposed by the fabric should be observed. These rules cannot be followed when an endeavor is made to produce anything novel or some new style for the market. There is a ceaseless demand made by some manufacturers for a new style or pattern, knowing the public craving for novelties. It goes on year by year. New carpet and wall-hangings designs; some new furniture or decoration "craze," like Japanese or bamboo; new fenders or fire-irons, stoves and overmantels are among the objects that have to be invented or designed to meet a fashion, and however exotic the taste or unappropriate the style, the order is obeyed. Of course, it goes by that elastic word of the manufacturer, "artistic," though its very nature is extremely inartistic—there is not the faintest indication that the so-called artistic qualities are an outcome of the workmanship or the material; rather they have been concealed or smothered with ornament or what passes for style. To take as an example the Louis XIV decorative furniture, known as Boule decoration. This kind of workmanship was carried to perfection by a few artists and craftsmen, of whom the leading one was André Charles Boule. It is a veneer or tortoiseshell and brass, with angle mounts, lines of mouldings, claws, feet, and other ornamentation; but the beauty of this kind of incrustation arose from the skill and taste of the art workmen engaged, and cannot be manufactured to order as many sorts of modern decoration are. Then there is no effort—no attempt to do something fresh for novelty's sake. The artistic furniture of France a hundred years ago, or the earlier schools of Italy and Flanders, was a branch of workmanship perfected by degrees; studios and workshops were formed of craftsmen who gave themselves up to the work. The art in the old cabinet and bureau was slowly and spontaneously developed. In point of time we had first the chest as a receptable for documents and articles; the fronts of these were panelled and carved; next the chest was placed on legs forming two stages, and we had the cabinet or sideboard. Besides being carved, the fronts have hinged flaps, and the interior is divided into drawers or recesses. The decoration grew as slowly; first carving, then ornamental hinges of metal next incrustation of precious woods, ivory, or metal, the supports ornamented with brass mounts. In this way the chest grew into the ornamental cabinet; each step suggested itself to the craftsmen in a natural way.

The art was then hereditary; the crafts or guilds were the guardians of traditional skill in their particular trades, thus insuring that truly honest, national character which distinguished all workmanship during the 16th and 17th centuries. This traditional skill is seen in the delicate mouldings and turnings, the quiet inlays of wood and ivory. The craftsman, who was a master of woodwork, went patiently but boldly to work, and was content with plainness until he could see a way to develop or ornament a feature. An authority on woodwork has said that the "best present day example of furniture is the deal table of the farmhouse or cottage," where modern vulgarisation has not entered. He is right, because it is a plain, straight-forward piece of framing, solid and well put together; to make it artistic is to give it pleasing proportions. If it is a parlour or sitting room table, the legs may be partly turned, with rails tenoned into them, and the edge of the table moulded. But to make it "artistic" according to the modern sense would be to make it as light in its framing as possible; to make the legs like turned brush-handles, or to stick on a few carved trusses under the top. In the framed carpenter's work of the 16th century we see means the most simple adopted—the construction and form and ornament, if any, appear to be the traditional method of the craft; but its very construction was pleasing, and at one with the ornament, which may be a simple incised ornament or geometrical device on the panel, and delicate members moulded and stopped on the rails and stiles.

What we have said about certain manufactured goods and furniture is equally true of the architectural crafts. There has been a great deal too much forcing, trying to produce ornament by extraneous means. All kinds of American and other inventions have been introduced to turn out ornamental woodwork; but it is not artistic, because it did not spring naturally from those simple conditions which lie at the foundation of all good architecture. For instance, the processes of producing ornament by embossing wood or of burning away certain portions are not those which now commend themselves to us. The chisel, moulding machine, and carver's tool, like the operation of framing, appeal to our reason as the natural processes of conversion. These processes admit only a certain kind of decoration, moulding the stiles and rails, and carving or incising the panels. Stone and brick and metal and plaster have each its own methods of conversion, its own modes of decoration, and if we try to invent any other the work at once loses the characteristic of being artistic. Between modern and ancient art, then, there is this difference—one is a meretricious, superadded quality, the manufacture of art; the latter a spontaneous development from material and skill.—*Building News.*

SANITATION AND HEALTH

DISCONNECTING PLUMBING FIXTURES.

Disconnecting house fixtures from the soil pipe is sometimes practiced with us with good effect, says the *National Builder*, and the principle may, we think, be extended with good results inside our houses. A recent adaption in the bathrooms of a block of flats consists in placing a small sink in the tiled floor, which in turn is laid on a span of plank like the "mill floors." Beneath the floor a "puro" tap is placed on the waste pipe of the little sink towards which the tile floor is slightly graded. The sink is so placed that the wastes of a porcelain lined iron bath and oval basin drip into it with the least possible length. These short wastes are of three-fourths inch nickeled pipes connected to the fixtures by simple means and simply movable. By this means only two holes are made in the floor for waste pipes, one for the closet and one for the sink. This little sink takes care of any overflow that may take place, and the wash of the floor as well. The basin, so apt to lose its seal by self-siphonage, is disconnected, and the usual cumbersome and expensive wastes of the bathtub are done away with. The small open waste pipes of the bath and basin have only small fouling surfaces, and these are easily scoured out by the rapid flow of the hot waste liquids. The number of soil pipe connections is lessened and the work generally simplified by the means taken to disconnect them. Practically the plea is that it is only a little evil, and by tolerating it things will look as much better. The sanitary engineer everywhere finds people objecting to good work because "it looks so." Show the architect or owner how some favorite trick of construction is dangerous to life and health and suggest that the work should not be concealed. The reply is "but it will look so to have it exposed." With a properly arranged bath and basin there is no difficulty in going through a tiled floor with a single opening in addition to that for the water closet.

"The number of soil pipe connections is lessened and the work generally simplified by the means taken to disconnect them." There is no possible excuse for having small fouling surfaces of this character. In the ordinary well constructed bathtub the trap is within the length of a union from the tub, and the distance inside of the bathtub from the surface of the seal scarcely exceeds three inches, and is sometimes less. In many of our best forms of basin the whole length of pipe from the seal up to the basin can be reached for cleaning. The idea that "hot waste liquids will clean out a pipe three-quarters of an inch in diameter" is a matter of faith rather than of works. Every architect should be firmly imbeud with the idea that the plumbing work is the most honorable of all that goes inside the house; there is no excuse for sacrificing it to any other requirement of construction or convenience. Its perfection is of a paramount importance.

It has been found by careful experiments that one square foot of wall space will transmit from 70 to 1.25 units of heat per hour for every degree difference in temperature between the inside and the outside, the difference being caused by the action of the wind; In order to ascertain the amount of heat that will be transmitted through one square foot of wall space it will be well to take the lowest probable outside temperature and the highest transmitting capacity of the wall. Then from the desired temperature of the room subtract the lowest probable outside temperature and multiply the remainder by 1.25. This will give the number of heat units transmitted by each square foot of wall space for the space of one hour, multiply that amount by the area of the wall exposed in square feet, and the result will be the total heat units for one hour.

To find the heating surface we proceed as follows:—From the temperature of the steam subtract the temperature of the room; square the difference and divide by 100, which will give the number of heat units for each square foot of heating surface. Divide that into the total heat units required, and the quotient will be the number of square feet of heating surface for that pressure of steam. A three foot length of one inch pipe equals one square foot of heating surface. When a whole building is to be calculated the roof must also be included. All steam pipes act as heating surface. The diameter of the main in inches should be one-tenth the square root of the heating surface in square feet. It is as well to use one inch pipes for heating with live steam. For heating with exhaust steam two inch pipes are preferable. Return pipes should never be less than three-fourths the size of the mains.

METHODS OF MAKING HARD BRICKS.

In the western parts of Monogolia there are such rapid alterations of temperature that ordinary bricks and even the usual building stones disintegrate very rapidly. The inhabitants of that country have a process for making extremely hard bricks, sonorous, and having the appearance of trachyte. The article by E. Blanc in *Dingler's Polytechnisches Journal*, describing the process, does not inform us as to the exact constitution of the clay. The brick kiln is in the shape of a vertical cylinder, surmounted by a dome. There is a rather wide dome, and during the first part of the process the hole is left open. Three draught chimneys built inside the furnace open outwards at the height of the dome and are kept closed with clay at the begining of the operation. The kiln is heated for three days during the first part of the process, and then the hole at the center of the dome is gradually reduced in size, by means of blocks of moistened clay. The flame is allowed to die down and the small hole remaining covered with wet felt. The felt is covered with sand which is continually kept moist. The three lateral chimneys are then opened and the fire lighted again. The draught is thus reversed and the second stage of the process thus commenced lasts for four days. During this time the water from the felt is heated and fills the kiln with an atmosphere of superheated steam. At the beginning of the second part of the process the bricks have light red color and this changes to uniform dark gray. At the end of four days the bricks are completed.

PUBLICATIONS.

A feature of the *Cosmopolitan Magazine* for November is the portion of the magazine given up to color work, no less than ten superb color illustrations being presented for the first time in magazine history, accompanying an article by Mrs. Roger A. Pryor on Changes in Women's Costumes.

The By-Laws of the Toronto Builders' Exchange have been neatly printed in book form and enclosed in flexible cloth covers, with the name of the Exchange in gilt thereon. In addition to the By-laws the book contains a copy of the Declaration of Incorporation, and a list of the members of the Exchange. We are endebted for a copy to the Secretary.

Mr. H. E. Haferkorn, of Milwaukee, has just published a handy list of books on Fine Arts and Architecture, Painting Sculpture, Decoration, Ornament, Carpentry, Building, Art Industries, etc. This work is an alphabetical reference catalogue, arranged under authors and subjects, and including analytical references to the contents of important works and as such, furnishes in compact form a key to all the literature of value on the subjects named, and is calculated to save the seeker after information a great deal of time which without its aid must be spent in searching through numerous catalogues. The price of this handy list in paper covers, is $3.25; cloth, $3.50; leather, $3.80.

USEFUL HINTS.

CEMENT FOR GLAZED SURFACE.—This cement was invented by Prof. Alexander Winchell, the noted geologist. It adheres perfectly to glazed surfaces, and is excellent for mending broken minerals or fossils. Pulverize two ounces of gum arabic and dissolve it in the quantity of water a laundress would use for the same bulk of starch. Dissolve half an ounce of fine starch and half a ounce of white sugar in the gum solution; cook the mixture in a vessel set in boiling water till it becomes clear. A little gum camphor, oil of cloves or sassafras, will keet it sweet. A little alum adds to the effectiveness and helps preserve the cement.

MAKING BRICK IMPERVIOUS TO MOISTURE.—In reply to "H. G. G.," Galt, Ont, who asks, is there any cheap and reliable way to make bricks water-proof, so that they will be able to resist a water pressure of say 75 to 100 pounds? the *Manufacturer and Builder* says:—The only safe course to pursue in a case like this, would be, in our judgment, to saturate the bricks before laying up, by immersing them in hot asphalt (or a composition containing asphalt), and to bed them in the same material, so that joints as well as bricks would practically form a single homogeneous body of asphalt. Such a wall would, if laid with care, be perfectly impenetrable to the entrance or exit of water. It would not be a cheap way of doing work, but would be efficient in fully answering this inquirer's purpose. A cemented wall would not be water-proof, and especially not where it was required to withstand considerable pressure.

THE T GIRDERS USED BY THE ROMANS.—In discussing the use of iron on a large scale by the Romans, Mr. Gradner writes:—"From Pompeii we might infer the total absence of constructive ironwork in Roman architecture, yet Prof. Aitchison claims that in the Baths of Caracalla large ceiling was supported on iron girders." This fact might be stated less doubtfully than these words would imply, since some tons of broken iron T girders were found a few years ago during the excavation of the great cella soliaris of the Therma of Caracalla. These girders had been cased in bronze, and they were arranged so as to form square panels, which were well filled in with concrete decorated with mosaic and delicate stucco reliefs, all colored and gilt, thus forming a strong and richly-decorated flat ceiling, with a span of enormous width.

The effect produced on the character of cement for mortars by the size or form of the sand employed has been the subject of investigation by M. Feret, a French expert, who prepared artificial sand out of crushed quartzite, with a view to determining its strength as compared with sand of natural formation. The sand as received from the crusher was graded into three degrees of fineness. The first consisted of such grains as would pass through a sieve containing four meshes to the square centimètre, and were retained on a sieve of thirty-six meshes per square centimètre; the second consisted of grains passing through a sieve of thirty-six meshes to the square centimètre, and retained in one of a much finer mesh, while the third consisted of the grains passing this last sieve. Measured dry, each of these samples had practically the same specified weight, the second being slightly the lightest. Mixed in various proportions, it has found that the mixture having the highest specific weight was one comprising six parts of the first sand and four of the third, the weight of this being thirty per cent. more than that of number two.

CANADIAN ARCHITECT AND BUILDER.

VOL. VI.—NO. XII. DECEMER, 1893 { PRICE 20 CENTS $2.00 PER YEAR.

—THE—

CANADIAN ARCHITECT AND BUILDER,

A Monthly Journal of Modern Constructive Methods.

(With a Weekly Intermediate Edition—The CANADIAN CONTRACT RECORD),

PUBLISHED ON THE THIRD THURSDAY IN EACH MONTH IN THE INTEREST OF

ARCHITECTS, CIVIL AND SANITARY ENGINEERS, PLUMBERS, DECORATORS, BUILDERS, CONTRACTORS, AND MANUFACTURERS OF AND DEALERS IN BUILDING MATERIALS AND APPLIANCES.

C. H. MORTIMER, Publisher,

Confederation Life Building, - TORONTO, CANADA.
Telephone 2362.

64 TEMPLE BUILDING, - MONTREAL.
Bell Telephone 2259.

SUBSCRIPTIONS.

The CANADIAN ARCHITECT AND BUILDER will be mailed to any address in Canada or the United States for $2.00 per year. The price to subscribers in foreign countries, is $2.50. Subscriptions are payable in advance. The paper will be discontinued at expiration of term paid for, if so stipulated by the subscriber; but where no such understanding exists, will be continued until instructions to discontinue are received and all arrearages paid.

ADVERTISEMENTS.

Prices for advertising sent promptly on application. Orders for advertising should reach the office of publication not later than the 12th day of the month, and changes of advertisements not later than the 5th day of the month.

EDITOR'S ANNOUNCEMENTS.

Contributions of technical value to the persons in whose interests this journal is published, are cordially invited. Subscribers are also requested to forward newspaper clippings or written items of interest from their respective localities.

The "Canadian Architect and Builder" is the official paper of the Architectural Associations of Ontario and Quebec.

Subscribers who may change their address should give prompt notice of same. In doing so, give both old and new address. Notify the publisher of any irregularity in delivery of paper.

MUCH interest is felt in the competition for a new City Hall for the City of New York. The competition closed on the first of September. The number of designs submitted was 137, the competitors representing the United States, England, and we understand, Canada also. The proposed cost of the buildings is $7,000,000 It is estimated that the architect's commissions will amount to about $800,000. Much regret is expressed that owing to ill health Mr. Richard M. Hunt is unable to serve on the architectural committee selected to aid the building commissioners in deciding the competition.

AT the annual meeting of the Canadian Society of Civil Engineers, to be held in January, action will be taken on the report of the Committee on Professional Status. The report recommends that land surveyors should be prevented from practising as civil engineers, unless they belong to the Canadian Society of Civil Engineers; that an appeal should be made in each province to have members of the Canadian Society of Civil Engineers recognized as professional men, with right to collect fees; that no practitioner shall be entitled to designate himself as a civil engineer unless he belongs to the Canadian Society of Civil Engineers.

AS a means of making the meetings more instructive and entertaining the Chairman of the Builders' and Contractors' Association of Victoria, N. S. W., recently invited the reading of papers by the members of that body. Who should know, he said, more about the structural portion of edifices than the men who built them, and who were better fitted to expound the laws and regulations affecting them? Even if the papers were merely reminiscent, they would provide better subjects for discussion than the payment of fees and various irrelevant topics. The attention of the officers of the Toronto Builders' Exchange was recently called in these columns to this subject. Papers and discussions on topics connected with building would tend to enliven the meetings of the Exchange throughout the winter; the interchange of experiences and opinions would be mutually helpful, and in giving expression to their views the members would derive intellectual advantage. We hope an attempt will be made to put the suggestion into practice.

THE manufacturers of Canadian cement are complaining of the action of the Dominion Government in using imported cement in the construction of the Soulanges canal. This is the first instance so far as we are aware in which imported cement has been used in Canadian public works of this character. In the construction of the Welland and Sault Ste. Marie canals Canadian cement was employed, and the durability of the material in the case of the Welland canal at least has been amply demonstrated. No reason has been given by the Government for the use of imported cement in the Soulanges canal except that they felt bound to act on the advice of their engineer. It is due, we think, to the manufacturers of Canadian cement that they should know the reasons which prompted the engineer to advise the Government to purchase foreign material, more especially in view of the fact that the native material has undergone such satisfactory tests, and that the cement manufacturing industry in Canada affords employment to a considerable number of persons. In addition to this, the purchasing abroad of what can be obtained at home, is contrary to the policy of encouraging native industries which has been a prominent feature of the Government's platform.

IN response to representations made for several years past by the architects of Toronto, the Fire and Light Committee of the City Council have decided that hereafter on residential streets within the brick limit, Elizabethan architecture will be permitted, so that above the first storey, which must, as before, be of solid brick, timber framing, filled in with Portland cement or stucco, may be used. Several specimens of this style of architecture have been erected under special permit, and the new regulation will, probably, lead to the erection of many houses in the old English style, thus widening the scope of architects for the decorative treatment of their designs, and greatly enhancing the artistic appearance of residence streets. It was decided also, to place the new front, between Yonge, Simcoe, Esplanade and Lake streets, in the brick limit. South of Lake, wooden structures, covered with corrugated iron, galvanized iron and metallic shingles may be erected. On all wooden buildings hereafter galvanized iron and metallic shingles may be used.

THE owners of the building occupied by the Toronto Technical School have notified the management that in future the rental will be $600 per year instead of $300 as heretofore. This notice was not given until after the School had entered upon its winter work, and when removal to other premises could not be attempted. To a letter previously addressed by the Secretary of the School to the owners of the building requesting to know what rental would in future be charged, no reply was given. In view of this, the action of the owners in doubling the rental so late in the year bears the appearance of deliberate sharp practice. In a reference to the successful working of the school in a previous issue, the need of a new building adapted to its present and future requirements was mentioned. The large increase in rental now imposed should determine the erection of a new Technical School building if possible next year. The amount of the present yearly rental is sufficient to pay 5 per cent interest on $12,000, and this sum would form a considerable proportion of the cost of a new building.

THE building permits issued by the City Commissioner for the City of Toronto, for the year 1893, fall short of those of the preceding year by more than $1,000,000. This is partially accounted for by the fact that the permit for the new City and County buildings, amounting to $1,000,000, was included in last year's record. It is yet too early to speak with any degree of authority regarding the outlook for 1894. The opinion prevails, however, that the lowest point has been reached in the depression which has prevailed in Toronto for some years past, and that the tendency will be upward in the future. It seems clear that no building of a speculative character will be done in Toronto for some years to come, and this is regarded by reputable builders and others who have at heart the welfare of the city as something to be thankful for. It is believed that a fair amount of building will be done next year in the business portion of the city. Improvements to buildings used for business purposes have not kept pace with those for residence, and there now seems to be a disposition to even matters up in this direction.

THE sentence of one year's imprisonment which has fallen upon Messrs. McGreevy and Connolly should have a salutary effect upon the propensity for boodling which has prevailed to so great an extent of late in connection with public contracts in Canada, and more especially in the Province of Quebec. The petitions which are being circulated on behalf of the prisoners by persons whose sympathy appears to have overcome their judgment, will have a tendency to destroy the good influence which might otherwise be expected to result from the decision in this case. It is perhaps true that the men upon whom punishment has fallen are not the greatest wrong-doers in the case, but the fact that it is not possible to bring under the power of the law the chief conspirators is no reason for allowing the sinners of lesser degree to escape. It is high time that a check was put on crooked practices in connection with the awarding of public contracts. The system of securing contracts by means of bribery is practiced to such an extent that it has become impossible for firms who are unwilling to resort to this method to obtain any business in certain quarters. The influence of the system upon officials in the public service, and indeed upon the community at large, is pernicious and harmful in the extreme. Furthermore it leads to a great waste of public money, as contracts which are thus purchased are given at figures greatly above what would be obtained if honest competition prevailed. Viewing the subject in these aspects, it should be a matter of congratulation that punishment has overtaken some of those who have been engaged in crooked dealing, and the hope should be entertained that the Government and public corporations of all kinds would set themselves with determinatian to stamp out boodling.

THE improvement of the public highways is a subject which for several years has occupied a considerable measure of public attention in the United States, and we are pleased to notice is now being considered in Canada also. Mr. Andrew Pattullo, of Woodstock, Ont., has been largely instrumental in calling public attention to the subject in Ontario, and a convention to consider the question is shortly to be held. A little consideration is all that is needed to show that if the principal thoroughfares of the country were improved in such a way as to present a smooth solid surface on an unyielding foundation, greater loads than at present could be transported over them, and there would be a great saving in horses and wear and tear of vehicles. At the foundation of the present unsatisfactory and in many instances disgraceful condition of our public highways, is the system of carrying out repairs by statute labor. Under this system men are appointed to supervise and to build roads who have had no experience whatever to fit them for the work, but are in this way allowed to pay their taxes in labor. Under such circumstances it would indeed be surprising if the work were done in anything like a proper or scientific manner. Payment of taxes in rural municipalities should be made in cash, and such portion of the taxes as is to be spent in the improvement of the roads should be expended under the direction of an engineer or other experienced person. In this way more work would be done for the amount now expended, and what is of more importance, it would be done in a proper manner and would not require re-doing year after year. The subject of road improvement is one of primary importance to the farming community. The putting of our main highways in a condition approximating in some degree to that in which the roods are maintained in European countries, would vastly increase the farmer's profits and the value of farm property, and result also in benefitting largely the business community. Engineers and skilled roadmakers as well as manufacturers of road-making materials should be interested in this subject.

AN effort is being made to develop trade relations between Canada and Australia, the Hon. Mr. Bowell, Canadian Minister of Customs, having just returned from a visit to Australia with this object. Dr. Benwick, who acted as commissioner for New South Wales at the World's Fair, expresses the hope that a market can be developed in America for Australian woods, which are a complete contrast in character to those of this continent. They are mostly hardwoods, and are especially adapted for railway ties, block roadways and interior house decoration. The *Australasian Builder and Contractors' News* has a lengthy article on this subject, and cites the fact, mentioned in in the CANADIAN ARCHITECT AND BUILDER, that the City Engineer of Toronto had recommended the paving of the streets of that city with vitrified brick, as proof that there exists an opening in Canada for the use of Australian wood for paving purposes. We have no doubt from the fact that certain Australian woods are being thus employed to a considerable extent in the streets of London, that the material is well adapted for the purpose, but are inclined to question whether it could be transported to Eastern Canada and sold at a price which would enable it to be used in competition with vitrified brick and asphalt. It might be possible to find a market here for certain kinds of interior finishing woods, which might be partially manufactured in Australia and shipped so as not to occupy much space on steamers and cars. This could not very well be done in the case of paving material, hence we fear that its bulk, and the great distance over which it would have to be transported, would forbid its introduction and use in this country. There seems a probability that an exchange of materials can profitably be carried on between Australia and the Province of

British Columbia, and that a market could be found in Canada for certain Australian timbers which are specially adapted for railway ties. While the average life of a railway tie on the C. P. R. is from six to nine years the grey gum-wood, it is said that of Australia will endure for forty years for this purpose. There is also a demand in British Columbia for timber for piling purposes for use in wharves, breakwaters, etc., which will resist the destructive attacks of the *teredo* or sea spider. The native woods at present used for this purpose are protected with creosote and other preparations at a cost of 25 to 30 cents per running foot, and even after having been subjected to these expensive processes the life of piles averages less than ten years. It will readily be seen that the cost of renewing work of this kind at such frequent intervals is very great. It is said that the turpentine tree of New South Wales, when the bark is left on the wood, is absolutely proof against the attacks of the *teredo*. If this can be shown to be the case, and there exists an ample supply of this class of wood, there should be quite an extensive market found for it on the Pacific Coast. On the other hand there has been some export of British Columbia lumber to Australia, and inquiries are being received for British Columbia shingles. Galvanized iron appears to be at present largely used for roofing purposes in Australia, and it is believed that the British Columbia sawn shingle would be much better adapted for the purpose and would afford a more pleasing architectural effect.

THE O. A. A. CONVENTION.

The dullness of business which has given architects leisure to think will perhaps produce fruit in increasing the interest of the Convention which is to be held next January. We understand that invitations have been issued to several members to read a short paper at the Convention. These with the discussion that is likely to follow should make the proceedings lively and instructive. It is better that many should take part in the proceedings of a meeting of that kind than a few; and though a long paper is a serious undertaking, a short one, which does not attempt to treat of a whole subject but only one point, is within the powers of most men and does not require the expenditure of too much time. Paper reading is a valuable exercise for the reader himself. It enables him to "marshall his thoughts more orderly." When he has carried his subject about with him for a few days he finds his ideas about it much clearer and further reaching than they were when he began to write the paper.

ILLUSTRATIONS.

RESIDENCE ON LOWTHER AVENUE, TORONTO.– EDMUND BURKE, ARCHITECT.

MORTUARY CONSERVATORY AT MOUNT PLEASANT CEMETERY, TORONTO.— EDMUND BURKE, ARCHITECT.

The new mortuary has been built upon the foundations of the old vaulted structure, and no changes whatever were made to old front, facing Yonge street. The old building was covered with two semi-circular arches, above which was a single elliptic arch covered with earth. Dampness and decay had so affected the structure that it became unsafe, necessitating the entire removal of the arches to the level of the springing, about 4 feet above the floor of the mortuary.

The new walls were built on the old from this point up to the level of the roadway to the east, a total height of about 22 feet. A very heavy pressure of earth had to be provided for, necessitating large buttresses, thick walls with benches or steps on the outside, and the building of the whole in cement. The interior is faced with white brick.

The ceiling of the mortuary, forming the floor of the conservatory and forcing houses, is formed with 12" I beams at about 5 feet centres, with porous terra cotta arching plastered with Portland cement in the underside and covered with concrete above, forming a foundation for a granolith floor in the forcing houses and tile in the conservatory and mortuary chapel.

The walls of the conservatory and potting houses to the height of about 4 feet are of pressed brick, both inside and out; above they are of wood and glass, as are also the roofs. The chapel and potting house are roofed with red tiles. The conservatory and chapel may be turned practically into one room, the enclosure of the chapel being formed with sliding glazed sashes. The bier is made to descend by means of a hand power lift, and the opening in the floor of chapel is immediately closed by a pair of light folding doors. A low brass rail appropriately hung with curtains surrounds this opening, and a brass lectern is mounted at one end for the use of the officiating clergyman. A fan driven by an electric motor is provided for the ventilation of the mortuary chamber, so arranged that the air is drawn away from the vicinity of the opening for the bier. The heating is by hot water, the pipes, under the benches being 4" diameter and valved in sections for the control of varying temperature.

PAIR OF SEMI-DETACHED RESIDENCES, JARVIS ST., TORONTO, FOR MR. JAMES HEWLETT.—F. H. HERBERT, ARCHITECT.

Each of these houses contains a large reception hall divided from staircase hall by carved and fluted columns; drawing and dining rooms, the latter with handsome open pressed brick fireplace; kitchen, laundry and accessories, and bedroom, billiard room, 2 bath rooms, hot water heating, etc.

DESIGN FOR A SMALL STABLE,

with accommodation for two horses and two or three vehicles. Foundations to be of stone, first story of frame construction and clap-boarded, gables and roof to be shingled, and chimney built of brick. Estimated cost, $300 to $400.

ROAD REFORM.

Editor CANADIAN ARCHITECT AND BUILDER.

I am pleased to notice a decided step has been taken in the long discussed subject of road improvement. The Canadian Institute has done wisely in determining to call a convention for this purpose. It will be practically impossible for a great convention of this nature to be held, at which there will be a great gathering of those who are most directly interested in road reform, without practical benefit arising therefrom. The province is undoubtedly ripe for such an undertaking. Good roads mean more prosperity to farmers than railways, if they could only be made to believe it; the system of farming has made such great advances that farming of to-day is quite different to what it was 20 years ago. If the farmer then could afford to wait for two or three weeks for sleighing or until the frost was out of the ground he cannot do so now. Under the provisions of the municipal drainage, ditches and water courses and many other acts of parliament, municipal improvements of greater or less extent can be effected by means of assessments spread over a period of years. A similar system no doubt can be made applicable to road improvement; the assessment will be so light compared to the advantages obtained from improved roads the ratepayer will not feel it. I hope soon to witness great progress being made in this direction.

PROGRESS.

QUESTIONS AND ANSWERS.

[Readers are invited to ask through this department for any information which they may require on lines consistent with the objects of the paper. Every effort will be made to furnish satisfactory answers to all such inquiries. Readers are requested to supply information which would assist us in our replies. The names and addresses of correspondents must accompany their communications, but not necessarily for publication.]

W. A. S., Tweed, Ont., writes: I understand that a person holding a School of Practical Science diploma in Architecture is required to serve under articles of apprenticeship for three years, under a member of the Association of Architects. Please let me know through the Question Department of your paper, the terms under which an apprentice serves. Has he to pay, or does he receive anything during his apprenticeship.

ANSWER.—The Ontario Association of Architects has made no rule as to money arrangements between apprentices and principals and we believe there is no rule in the practice of the members of the Association in the matter. The premium seems to be seldom if ever exacted. Some firms have no money consideration either way; some give a small salary, increasing each year.

PERSONAL.

Announcement is made of the intended marriage on the 15th of January, of Mr. Emile Dubé, a well-known contractor of Riviere du Loup, Quebec, to Miss Isabella Lemieux, of the same place.

In painting wood that has been long exposed to the weather, it is economical to add whiting to the oil paint for the first coat, and if the subsequent coats are of lead, or lead and zinc, the job will be thoroughly durable. About a quart of whiting paste to the gallon of oil paint will be about the proportion required, and as much more oil and turpentine may be added as may be necessary.

OTTAWA.

(Correspondence of the CANADIAN ARCHITECT AND BUILDER.)

Attention is again being directed by the repairs now being made to the Geological Museum in this city, to the need of a new building which should be better adapted for the purpose. Efforts have been made on more than one occasion by the Royal Society as well as the civic authorities to induce the government to undertake the erection of a new building, but the great cost of a fire-proof structure such as would be required has deterred the government from moving in the matter. It is much to be regretted that the proposal made soon after the death of Sir John Macdonald to erect a building as a memorial to his memory and to serve as a National Museum and Art Gallery, was not carried into execution.

The new R. C. church of St. Joseph, an illustration of which appeared in the CANADIAN ARCHITECT AND BUILDER for October, was dedicated a fortnight ago. The building, which stands on the corner of Wilbrod and Cumberland streets, is constructed of stone, in the Romanesque style, and is surmounted by a lofty octagonal tower. The exterior, with the exception of the main entrances, which show some elaborate stone carving, is devoid of ornamentation. The interior, on the contrary is most elaborately decorated, as is the rule in Roman Catholic Church edifices. The cost of the building was in the neighborhood of $70,000. Mr. W. E. Doran, of Montreal, was the architect.

MONTREAL.

(Correspondence of the CANADIAN ARCHITECT AND BUILDER.)

The statues of Wolfe and Montcalm designed by Hebert for the facade of the Parliament Buildings at Quebec, will shortly be placed in position.

Prof Harry Bamford, M. S. C., late of Victoria University, Manchester, England, has received the appointment of lecturer in the Engineering Department of McGill University, Montreal.

The sum of $11,391,69 has been received and an almost equal amount disbursed by the treasurer of the Maissonneuve Monument to be erected in this city. The work of canvassing for the additinnal $15,000 required is to be at once proceeded with. Mr. Hebert is the sculptor.

St. George's Anglican church on St. Joseph street, is about to celebrate its Jubilee. It is proposed to mark the occasion by the erection of a tower and additions necessary to complete the building at a cost of some $16,000. The church, which occupies a commanding position, is a good example of Gothic architecture. It was the third Anglican church erected in Montreal, the corner stone having been laid by Bishop Mountain on the 8th July, 1842.

In reply to an enquiry, the Hon. Mr. Nantel, Minister of Public Works, stated in the Quebec Legislature recently, that the total amount expended on the enlargement of the Montreal Court House, since 1887, was $649,946.25. This does not include a heavy bill for extras for which the contractor has brought suit. The opinion prevails that the work has been far more profitable for a few individuals than for the people who will have to provide the funds to meet the cost.

The first monthly meeting and dinner of the Province of Quebec Association of Architects was held on November 25rd. The dinner took place at the City Club and was followed by a meeting in the Association rooms. Mr. A. C. Hutchison gave a lecture, illustrated with lime-light views, on the Architecture of the World's Fair. There was a good attendance of members and students. The second dinner and meeting will take place on Thursday, the 14th inst., when there will be a discussion on the advisability of admitting honorary members, and on other subjects of interest to the Association. The students are invited to attend.

Your remarks concerning the necessity for ample provision being made by architects in their calculations for the increasing wind pressures to which apparently buildings in this country are to be subjected, prompts me to remark that in this locality at least, it would seem wise on the part of architects, in the light of recent experience, to make provision against earthquakes also. Solidity is a characteristic of most of our buildings, and to this no doubt is due the fact that so little damage resulted from the recent earth disturbances in this city. In the general alarm which seized upon all classes of our citizens this fact appears to have been overlooked, for there was an effort on the part of everybody to get into the open air.

The new addition, recently completed, to the Art Museum was formally opened by His Excellency, the Governor-General, a fortnight ago. The new building is designed to afford improved class rooms and an additional gallery for exhibition purposes. The Art Association of Montreal was organized in 1879, art classes being formed shortly afterwards. Besides the annual exhibitions there have been held sixteen loan exhibitions. There has also been accumulated a valuable permanent collection of paintings, the nucleus for which was donated by the late Mr. J. Tempest. In connection with the opening ceremony, the hope was expressed that something would be done for the development of art in conjunction with industrial education, in order that the knowledge of art might be employed for the purpose of beautifying manufactures. Mr. A. T. Taylor was the architect of the new building.

An interesting test was recently made at McGill University of the strength of a beam of British Columbia spruce furnished for the purpose by Messrs. T. J. and F. J. Claxton. The beam, which was 25 feet 5 inches in length, 8¾ inches in width, and 17½ inches in depth, was cut from a tree felled about 700 miles north of Victoria a year ago. It was subjected to a transverse test on supports 24 ft. apart on centres, the centre load being applied by increments of 500 lbs., and the deflection noted for each increase The beam failed under a maximum load of 38,250 lbs., and not, as is usual, by the rupture of the fibres on the tension side, but by the crippling of the side in compression. The skin stress developed was also unusually high, being a little over 6,000 lbs. per square inch, while the coefficient of elasticity was 1,670,000. The strength of the British Columbia spruce is, therefore, double that of ordinary spruce or pine.

It is somewhat difficult to understand the recent agitation for the removal from its present site of the Nelson monument in this city, in the light of the fact that the monument was erected by the joint efforts of the French and English residents of the city, the first steps being taken towards its erection at a social assembly at which the news of Nelson's death was announced. Seeing that both nationalities contributed to its erection, and that it has remained in its present position for so many years without objection of any kind being made, it must be assumed that the recent agitation was due to the articles of an inflammatory nature which were published in certain of the papers, and to this cause no doubt must also be attributed the action of the youths who were recently discovered in an attempt to destroy the monument by means of dynamite. The entire agitation has been frowned upon by the more influential class of citizens of both nationalities, whose desire is that the harmony which has prevailed to so large an extent in recent years should continue. While punishment should be meted out to the young men engaged in the attempt to destroy the monument, the fact will no doubt be borne in mind that the papers referred to were the real cause of the unfortunate occurrence, and the severity of their sentence mitigated accordingly.

WINNIPEG.

(Correspondence of the CANADIAN ARCHITECT AND BUILDER.)

If the large number of buildings erected here during the past season is any criterion, Winnipeg has seen the last of the depression which followed her unfortunate boom, and architects and builders may now look forward in pleasant anticipation of "seven years of plenty."

The spell of cold weather which we have been enjoying, or otherwise, during the last few days, has interfered somewhat with the completion of work started late in the season, and the proprietors and contractors interested are watching anxiously for the thaw foretold by the "oldest inhabitants."

A good sign of the times is the excellent business blocks that are being erected in the country towns of Manitoba and the North-West. In many cases the walls are built entirely of stone, or with stone foundation and brick superstructure, and in every case the ground floor is provided with plate glass windows, and would be no discredit to longer established communities.

Plans for the Wesley College which the Methodists propose to erect on Portage Avenue next year, are now being prepared, and the design promises a model educational building. It is to be of stone, four stories in height, and basement. The work throughout to be most substantial. The cost will be about $80,000. This building will add another monument to the energy and enterprise of the above denomination in this country.

The Bank of Ottawa is the most important building erected on Main street this year, and is a good substantial edifice, four stories high. The design might do for a local man, but when one considers that it was prepared by an architect of Toronto, the "Athens" of Ontario, it is certainly disappointing, for it was expected that this enterprising Bank would have provided for the edification of the western rustic a higher type of architecture than he has been accustomed to.

The result of the bye-election which has just taken place here, may materially affect the building trades, and assist the prosperity of Winnipeg. If Mr. Martin, our newly elected member, is successful in persuading the Dominion Government to remove the rapids in the Red River so that firewood, lumber, stone, etc., may be brought here by water from Lake Winnipeg, thus lessening the expense of building by supplying the principal materials used, at a reduced cost. This matter has been under the consideration of the Dominion Government for years, and though fully convinced of its importance, they have allowed procrastination to reign supreme, and like Felix, of old, put off for a more convenient season.

The architecture of Winnipeg is now in a transition state, and the wood, brick veneer and galvanized iron age, is passing away, and is being succeeded by the stone, brick and copper age. In former years the buildings here, with few exceptions, were entirely frame, or frame and brick veneer, with wood sills for foundations resting on the sod, or supported on wood posts or piles; but the public are beginning to realize that it is poor economy not to build for the future as well as for the present, and while they cannot afford to immortalize themselves in blocks of marble, they can build in a substantial and durable manner, with less costly materials, which will not only give them a permanent investment, but will add materially to their comfort, especially during our winter months.

The school board is just completing two very fine 8 room school buildings, one in the south end of the city, and the other in the north end. They are constructed of stone and brick, two stories high with basement, and large hall in roof, which is well lighted by a large skylight. The school board is composed of some of the best men of the city, and deserve credit for the wisdom and forethought they have displayed in the performance of their duties as School Trustees, in purchasing, when increase of population demands more school accommodation, large blocks of land in desirable locations, which will give for all time ample play grounds for the children, and breathing places for the public when the city becomes closely built. On these sites are erected substantial buildings, planned and furnished after the most improved types, and to meet the advanced ideas of the present day.

Among the many legacies inherited from the boom is the saying "good enough," which is frequently made use of by workmen, when their work is objected to. They learned it in the days when houses were rushed up in a week, and the motto was to build honestly if you can, but build, and when a load of timber would be followed to the site of a proposed dwelling by parties anxious to rent or buy in order to secure a dwelling place. The result of the above, and of contractors taking work too cheap, is that to-day an architect has to be very watchful of his buildings in progress in order to obtain a fairly satisfactory job. However, the workmanship is improving and the materials are of a better quality than formerly, for the public are growing more fastidious and require a higher class of work. If contractors would refrain from taking work too low in order to obtain a job, and insist on receiving a proper price, so that there would be no necessity for them to scamp their work in order to obtain a profit, the architect's lot would not be such an unhappy one.

PERSONAL.

Fowler & Bowe, architects, Montreal, have dissolved partnership.

Mr. A. L. Hushands, Architect and Civil Engineer, of Conkshire, Que., has recently been elected a member of the Canadian Society of Civil Engineers.

Ald. J. C. Waine, a prominent builder and contractor, of Sydney, New South Wales, accompanied by his wife, spent a short time in Toronto recently, en route to the World's Fair.

In a recent issue of the *Australasian Builder and Contractors' News*, appears the following:—Mr. W. H. Wheeler, late-Assistant Hon. Secretary of the Architectural and Engineering Association of Victoria, and winner of last year's Prize for the best Design for a Mechanics' Institute to cost £8,000, offered by the Royal Victorian Institute of Architects in connection with the Classes of the above-named Association, sailed on Thursday by the new Canadian liner, Warrimoo, for Vancouver, British Columbia. Mr. Wheeler has been residing for some months in Sidney and its vicinity; but with so great a dearth of architectural-business in that city, as in every other portion of these colonies, he has wisely decided to seek "fresh fields and pastures new" in the great northern Dominion, where we trust his undoubted abilities and steady industry will find employment. Mr. Wheeler carries with him the good wishes of his many old friends in Melbourne, and of not a few, more recently made, in Sydney.

CONTEMPORARY ARCHITECTURE.*

In a previous portion of this address I defended—I hope, in your judgment, successfully—the works of contemporary architects from the reproach of want of originality. It does not, however, follow that the perception of the beautiful displayed in such works is commensurate with the originality of their design. I have, indeed, on a previous occasion recorded my conviction that the craze for novelty in the present day—not alone in art—is excessive, and not infrequently results in the grotesque. Is novelty the goal of our attainment? Is it not rather Beauty? When the Greeks produced what is the purest form of art, so far as we know, that the world has seen, it was not the outcome of a rage for novelty, but of the effort to crystallize in a beautiful form the requirements and conditions of life. It was in the days of their decadence that an intelligent observer recorded of them that "they spent their time in nothing else but either to tell or to hear some new thing." Can it be that such decadence is overtaking us? Judging by some modern works, their authors might not inappropriately be referred to in terms similar to those applied to the late Athenians; for their desire appears to have been, not so much to produce what is beautiful, as to evolve "some new thing." A column was originally designed to support the superincumbent weight known as the entablature, and in such juxtaposition is dignified and consistent; but divorced from such relationship, and applied to the face of a building with nothing to support, it is degraded to the position of an incongruous feature of ornamentation. An Order, again, is composed of certain parts, which, in the relationship they were designed to occupy, produce admittedly proportions that are dignified and beautiful; but when applied—one can scarcely say designed—in a ridiculously attenuated form, with parts misplaced or omitted, the result is grotesque. The conglomeration of familiar forms and features, divorced from the conditions they were designed to fulfil, and thrown together regardless, apparently, of any consideration but the attainment of novelty, produces the incongruous and silly effect that might have been foreseen. Yet by critics who ought to know better this sort of architectural quackery is lauded as original design, and its authors are praised as men of exceptional ability. Whatever it may be, it is certainly not the original work in the true sense of the words, but the parody that passes muster for it with the ignorant. The impress of original power is stamped on features not necessarily new, and imparts to them distinctive life and character, instead of rendering them ridiculous by divorcing them from their proper purpose. Contrast with such grotesque productions the works of the late Sir Charles Barry, and tell me in which you find the truer originality or the purer taste. In Barry's classical work there are dignity, repose, proportion, ample undisturbed wall-space, every feature and moulding adapted to its position, and in all the stamp of individuality without any appearance of straining after novelty. In the hotch-potch work I refer to, there is neither dignity nor repose; features and mouldings are indiscriminately applied, instead of being designed as inherent elements in the composition; and the deplorable absence of purity is in no way compensated by fulsome profusion of ornamentation. This practice of covering every bit of wall-space with ornamentation, composed of details pretty and original in design, but applicable, from their petty scale, to cabinet-work and not to buildings, is the curse of our modern street architecture, and demonstrates an absence of grasp and appreciation of breadth which it is sometimes painful to observe. In walks about London one longs to apply the scalping-knife in stripping off meretricious ornament, in order that the eye may find repose on some bit of undisturbed and undisfigured wall-space.

It is not often I have found myself in sympathy with the utterances of the venerable statesman who now occupies the position of Prime Minister, and it is consequently agreeable to be able to concur in views which he expressed a few months since when speaking of Industry and Art. "There is a circumstance in architecture," Mr. Gladstone said, "which terrifies me, and that is the tendency which appears to prevail in modern domestic architecture. I am speaking of their exteriors, and I refer to their redundant ornamentation. There are a great number of new buildings in London with regard to which, if you look at them, you will find that the architect had either a horror or a dread of leaving bare a single square foot of wall, as if there were something indecent in leaving bare a square foot of wall. . . . . Excess of ornamentation is, of all things, the most hostile to a due appreciation of proportion, because it is in proportion to the preception of breadth and beauty and line, and in the adjustment of lines to one another that the essence of the art lies, and in that you will find the hope of attaining high excellence in great works." Not in great works only, I would add, but in all works, great or small.

But while I deplore this meretricious tendency for redundant ornamentation, and while I decry the craze for oöelty, which together are responsible for disfiguring many of our modern domestic buildings, I yet desire to record my conviction that there is much that is hopeful and promising in contemporary architecture. Even the rage for educing some new things, exaggerated as it is, demonstrates that men prefer to think for themselves rather than to reproduce the works of others. If only the remarkable ability which is displayed in the designs of many recent buildings were directed less to the production of novelty and more to the study of proportion, less to the elaboration of ornament and more to the aspiration for simplicity; if only architects were to lead the taste of the day by impregnating their designs with "the perception of breadth and beauty and line," instead of pandering to the false and meretricious taste of a luxurious age; we should be able to congratulate ourselves—and perhaps at no distant date—on having reached the attainment of an architecture, pure, simple, dignified, and beautiful.

*From the annual address of the President of the Royal Institute of British Architects.

PEMBROKE WATER WORKS.

On November 22nd, 23rd and 24th, the system of waterworks at Pembroke, which has been under construction during this year, was tested by the Chief Engineer, Willis Chipman, of Toronto.

All the water is taken from Lake Allumette through an intake pipe half a mile in length and pumped by Duplex pumps to a Water Tower placed at such elevation as to give an efficient fire service over the business portion of the town. If a serious fire should occur in any of the high residential portions, a check valve at the Tower can be closed from the pump house by an electric switch.

The system consists of about 5 miles of piping with 52 fire hydrants, and the cost will be about $50,000. The pump-house is a very neat structure.

ROOF AND ROOF COVERING.

In actual execution the roof, of course, precedes the roof covering; but in working out the design it is frequently the covering which decides the shape of the roof. When once settled, it fixes at least the lower limit for the pitch, and it may even have an influence on the question of hips or gables. In olden times this influence was marked. In many districts hip tiles were scarcely to be had; lead hips were too costly for common use, and hips made up with slates and mortar were both unsightly and insecure. This difficulty has long since vanished. Facilities for transit are, from one point of view, even too great. Materials can be so readily taken from place to place that local peculiarities in building are tending to die out. The country and one might almost say the world, is getting too much alike all over it, and amongst other things we now find tile hips and ridges everywhere. They have, however, usefulness at least to recommend them. They supply a practical want; but this is more than can be said of all the materials which are nowadays becoming fashionable in localities to which they do not belong. Travelling has become easy; but when all places becomes pretty much alike, what will there be to travel for? It is time that all architects set themselves, as some have done, to fight against this impending uniformity, and it is worth noting how many roofing materials, and how many ways of using those materials, may still be found within the boundaries of England alone.—*Manufacturer and Builder.*

THE VALUE OF TECHNICAL EDUCATION TO ARTISANS IN THE BUILDING TRADES.*

If there be room for difference of opinion in regard to the value of technical education in other industries, there can scarcely be any in regard to this. Undoubtedly of late years, and in the colonies especially, the standard of quality in building work is much lower than that of thirty years ago in the Old Country—the difference being very noticeable to those who come fresh to it from Europe. The reasons for this are several. No doubt the rough and ready style of work in pioneer days, however necessary and valuable in its day, set, quite naturally, a low standard which it has been difficult to raise above. The influence of adventurers and speculators (a race not unknown in Australia) has had also a prejudical effect on the quality of work, and further, the relative expensiveness of labor in comparison with the cost of material has made cheapness of production the end aimed at, rather than quality of product. It will be admitted, I think, that the building trade is second to none in importance. Not only are the numbers of workmen very large, and all trades of an honorable and manly type, but, unlike the cotton-spinner of Manchester, or the cutler of Sheffield, the building artisan finds his trade wherever human beings congregate. He is limited by no locality, or time, or climate. If technical education, as applied to these trades, had no further effect than the raising of their intelligence and status, it would be a powerful factor in the well-being of the community. But apart from the number of artisans directly interested, the welfare of the community is largely bound up with that of the building trade. Next to the supply of food and water, I suppose the provision of healthy, comfortable, well-built houses takes a first place. We all need shelter, and the importance of the kind of dwellings we occupy is evident to all. As for the moral effect on a community it is not easy to estimate the strength of the sentiment which fills the breast of the true born Briton, whose house is his castle (in spite of it being sometimes "in pawn") and to whom the roof and the hearth are still the types (next to the marriage tie) of security, content and permanence.

An experience of over twenty years of active practice as an architect, and the conduct of large classes in technical subjects, bringing me into close touch with some hundreds of young artisans engaged in the various trades, have strongly impressed me with the sense of the value of technical education to the trades in question. I believe it to be the universal experience of architects that an all-round intelligent workman is the exception. A man who can read a plan with readiness, grasp general instruction, and enter fully into the meaning and spirit of a design is rarely to be found. Such a simple elementary work of construction as a king-post truss is seldom understood, and in problems of setting out work, and so on, the most obsolete of rule-of-thumb methods which a knowledge of elementary geometry could suggest. What frequent complaints are made of the ignoring of any necessity for an abutment to resist the thrust of a flat arch, the broken curves of plaster work, the defective construction which manifests itself in huge settlements and cracks, the inability to avoid or detect or remedy most painful blunders in design, decoration and workmanship. How often may one see in local Exhibitions and the like some piece of work designed and executed by an intelligent artisan—a work reflecting credit on a man's industry—and that is all. Yet he will stand by it with a glow of satisfaction on his honest face, amid an admiring group of his friends and neighbors. It may be a dovecot having a flimsy front in ½ in. pine, in imitation of the facade of Milan Cathedral, or an aviary of similar construction with Roman pilasters, Early English arches, and a Greek pediment, with Egyptian ornament and pinnacles of 15th Century French Gothic. Turning then to the specific advantages which technical education should render to artisans, undoubtedly the art of drawing takes a first place. There is no branch of industry in which the ability to use the pencil with freedom is not of great value, and the helpless manner in which the ordinary workman attempts to express his ideas by drawing is notorious. Drawing is a splendid education of both eye and hand; the young student is taught to draw out and improve the natural powers of his hand before it has become stiff and flexible and habituated by custom to certain set motions. It trains both the eye and the hand to be more efficient instruments of the mind, and is an excellent discipline for the mind itself. I would rather have every young artisan instructed in the use of scales, the art of reading a plan with readiness, the practice of projection, and obtain such a general insight into the art of building construction that all branches of the trades may be seen in their true relation with each other. He should also have some teaching in the art of physical science—some real knowledge, however limited in extent, of the ordinary laws of nature—useful not only for the grasp of facts but as a training in the scientific spirit and way of looking at things.

Passing, now, to the various trades, let me briefly enumerate some of the salient points in which a knowledge of the principles of Art and Science will be of direct value to the workman. Take first the mason, a man who, in my opinion, is second to none in intelligence and ability. The geological history of the stones which he has to work will guide him in selecting, working and setting of them. Geometry is required to set out his working lines and moulds and patterns, and a knowledge of the laws of mechanics and of general design will also be of service. The bricklayer will find a knowledge of applied mechanics and statics of great advantage; also such a knowledge of chemistry as will guide him in the use of limes and cements, the proportions of motar, concretes, &c. Geometry will of course be of service in setting out his work, though this is generally done by the carpenter—a usage which has tended, I fear, to render the bricklayer less interested in such matters than is for his advantage as an intelligent artisan. The carpenter requires such a knowledge of the proportions of timber that he may select and wisely use them. Geometry, projection, the nature of strains and stresses, and the nature, application, and characteristics of building materials, are as serviceable to him as to any workman on the building. The plumber should have an acquaintance with chemistry and metallurgy, the properties of solids, liquids and gases, and metals and alloys, construction of joints, principles of traps and other sanitary details and general principles of sanitation. The plasterer needs a similar knowledge of chemistry of limes and cements as is found useful to the bricklayer. He needs further a training in practical geometry, in modelling and the principles of Classic and Gothic ornament, in addition to the power of sketching, which all artisans require. The smith and founder should be well grounded in metallurgy, statics and applied mechanics, mechanical drawing and elementary geometry.

The slater, in the work of ordinary plain slating, works mechanically, and only needs a knowledge of geometry in the event of carrying out elaborate patterns. The painter and glazier requires a scientific acquaintance with the materials he uses, some knowledge of geometry and the laws of the color, as well as a training in decorative design and principles of Art.

I can understand the question arising, why has the technical education of the past twenty-five years effected so little improvement in the personnel and work of the artisan? There are, I believe, several reasons for the slow progress which has been made. In the first instance, primary education in the Old Country twenty-five years ago was very different from that which is now equipping the young for the battle of life. Technical instructors were also men who very largely needed themselves to be trained—a band of efficient teachers could scarcely be expected to spring from the earth with full equipment. A heavy mass of inertness had also to be set moving, and the beginnings were necessarily slow, difficult and tentative in their nature. I think further, that it must be admitted that the instructors were generally of the wrong class—as a rule, they were free-hand drawing masters, excellent men in their way, but with only just sufficient knowledge of technical branches of study to pass examinations for which they were required to coach their students, and with practically no acquaintance with trades and callings for which the students were being trained. The methods of teaching were, in consequence, often defective and the aims also were by no means above reproach. The tendency at any rate was to draw students away from their handicrafts to become draughtsmen. The temptation for young artisans to do this is unfortunately very strong, and when in the actual training of a man his handicraft was ignored it materially resulted in spoiling many a good mechanic and added to that large and shiftless body, the army of ill-equipped draughtsmen, architects and engineers. Admitting all this, however, I maintain that much has been done by technical education to maintain the status of the workman and, if not to improve, to arrest the decline in the standard of work. Dealing now with a matter within my own knowledge, I can point to young men who, having received a training in the principles of Art and Science affecting their trades, are of distinctly greater value to their employers, have risen to the position of foremen and overseers, and have a better prospect of permanent employment when work is scarce. It must be conceded that technical education is not a failure, when it imparts such a stimulus to young men that they desire to enter callings where manual skill, combined with dexterity and trained intelligence and eye, are essential conditions of success. It does excellent work if it helps beginners in life to take part in some work requiring special skill, instead of drifting into that vague profession of clerkship, which is too often taken to because a youth has no training or talent that would fit him for the more honorable calling of a producer.

Chrome green is made from a precipitate of chrome yellow mixed with a precipitate of Prussian blue.

CLAY EMBANKMENTS.—The support of embankments, where clay forms a considerable part of the material, is a kind of mystery to the unskilled owner and builder of such embankments. In Marine Country, opposite the city, for example, there are clay strata all over the slopes, and slides thus caused can be seen on every hand, so the conclusion is that clay will not stand as an embankment unless held by bulkheads of masonry or wood. The fact is, however, that clay stands very well at an angle of 45 degrees, or 1 to 1, if saturated. It is all a question of water. No other material is so much affected by saturation. It is at the same time the best and worst material for an embankment. A range of 16 to 45 degrees between drained and undrained embankments is phenomenal. Clay embankments require drains to be placed at frequent intervals, and should have laths of wood, straw or other substance laid in, to form leading channels or perforations connecting to the drains.—*Industry.*

* Abstract of paper presented to the Australian Association for the Advancement of Science by Mr. Hillson Beasley, A. R. I. B. A., Lecturer on Architecture at the Working Men's College, Melbourne, &c., &c.

CANADIAN LIME FOR THE AMERICAN MARKET.

THE report comes from Boston that a syndicate of American capitalists, among whom is Mr. Frank Jones, who is interested in kilns at Sherbrooke, Que., is about to purchase the lime-kilns of Bras d'Or, on the island of Cape Breton, Nova Scotia, and at St. John, N. B. This action is to be taken in view of the probable reduction of the duty on lime under the amended American tariff.

The Boston despatch referring to this matter says that it is believed that under a low rate of duty a very large market for Canadian lime would be found in the New England States. Before the McKinley bill went into effect Canadian lime was admitted under a trifling tariff of about three cents a barrel. It overran the market in Boston, and practically had control of the trade. Despite the fact that Bras d'Or lime is not of as good a quality as Rockland lime, the difference in price incident upon the low tariff and the cheaper labor of Canada compelled the builders to use this lime. The McKinley bill put a duty of about 13 cents a barrel on Canadian lime and this had the effect of evening up the prices. The new tariff bill practically puts Canadian lime back to where it was. It is quite probable that again the builders will have to take notice of the big difference in price and fall back to the use of Canadian lime. Though wages are higher in Maine than in Canada, under a tariff the price of lime has actually fallen, so that it is selling cheaper now than at any other time in its history.

WIND PRESSURE.*

A paper on the above subject was read at the recent meeting of the Australian Association for the Advancement of Science, at Adelaide, by Professor Kernot, of the Melbourne University. The paper, which was of considerable length, commenced by referring to the great inconsistencies appearing in engineering and architectural practice, with regard to wind bracing of chimneys, roofs, bridges, etc., and to the great variation in the anemometric results given by the meteorological observatories; some observatories, such as Bidstone, near Liverpool (England) and Sydney recording pressures, or velocities corresponding to pressures of 90 lbs. or 100 lbs. per square foot, while others, such as Greenwich and Edinburgh, Melbourne and Adeliade, give results only one-third as great; and it was pointed out that these latter results correspond fairly well with usual experience with railway carriages and chimneys, great numbers of which would overturn with pressures of not more than 30 lbs. per square foot, and yet as a matter of fact do not overturn, and are regarded by the public as perfectly safe. Reference was next made to the experiments tried by Sir B. Baker at the Forth Bridge, which showed that the average pressure on surfaces as large as railway carriages, houses or bridges, never exceeded two-thirds of that upon small surfaces of one or two square feet such as have been used at observatories, and also that an inertia effect which is frequently overlooked may cause some forms of anemometer to give false results enormously exceeding the correct indication. The very elaborate experiments of Mr. O. T. Crosby, detailed in *Engineering* of 13th June, 1890, were next dealt with. These experiments showed that the pressure varied directly as the velocity, whereas all the early investigators, from the time of Smeaton onwards, made it vary as the square of the velocity. Experiments made by the author of the paper, at speeds varying from 2 to 15 miles per hour, were described, which agreed with the earlier authorities, and tended to negative Crosby's results. It was pointed out, however, that further tests on a greatly extended range of velocities were needed. The paper next described an apparatus devised by the author for determining the relative pressure of the wind on flat plates, cubes, cylinders, spheres and other geometrical forms. This apparatus consists of a screw propeller similar to that used on steamers, 28 inches diameter and 48 inches pitch on a 30-inch tube. This propeller is caused to revolve at speeds varying from 400 to 800 revolutions per minute by means of a gas engine. The helical currents of air proceeding from the propeller are gathered up and discharged in one approximately steady jet of 12 inches by 10 inches section, by means of a radial diaphragm and a conical mouthpiece, having its axis tangential to the helical direction of the air. In front of this jet was placed the object to be tested, supported upon a very delicately made carriage running on an accurately levelled surface plate, the force exerted being measured by a delicate spring balance, the accuracy of which has been verified by means of standard weights. A large number of experiments were made with this apparatus, and many interesting and valuable facts elucidated. The ratio existing between the normal pressure on a sloping surface, such as a roof, and that upon a vertical plane was found to agree with the table given in Stoney on Stresses, p. 524; but it was found that this result applied only to roofs supported on thin columns under which the wind could blow freely. When the roof was placed upon a wall, as in an ordinary building, the wall deflected the current of air upwards, and greatly reduced the pressure on the roof. If the wall was provided with a parapet of ordinary proportions this effect was still more marked, the pressure being reduced to one third of what it would otherwise have been. In the case of a roof of 30 deg. pitch the pressure was actually reversed the roof having a slight tendency to lift. In these experiments the parapet was made only one-sixth the height of the roof measured from the level of the eaves to the ridge. Experiments were also tried as to the effect of a wind blowing in at the open end of a building having the sides and other end completely closed, and it was found that the internal pressure tending to lift the roof was equal to the pressure of the wind on a flat vertical surface. The pressure upon one side of a cube, or of a block proportioned like an ordinary carriage, was found to be ·9 of that upon a thin plate of the same area. The same result was obtained for a square tower. If the cube or tower was placed so that the wind blew in the direction of a diagonal, the total pressure was just the same as when one side was presented. A square pyramid whose height was three times its base and which represented a common form of church spire experienced ·8 of the pressure upon a thin plate equal to one of its sides, but if an angle was turned to the wind the pressure was increased by fully 20 per cent., a curious contrast to the action on a cube or square tower. A bridge consisting of two plate girders connected by a deck at the top was found to experience ·9 of the pressure on a thin plate equal in size to one girder, when the distance between the girders was equal to their depth, and this was increased by one-fifth when the distance between the girders was double the depth. A lattice work in which the area of the openings was 55 per cent. of the whole area experienced a pressure of 80 per cent. of that upon a plate of the same area. The pressure upon cylinders and cones was proved to be equal to half that upon the diametral planes, and that upon an octagonal prism to be 20 per cent. greater than upon the circumscribing cylinder. A sphere was subject to a pressure of ·36 of that upon a thin circular plate of equal diameter. A hemispherical cup gave the same result as the sphere; when its convexity was turned to the wind the pressure was 1·15 of that on a flat plate of equal diameter. When a plain surface parallel to the direction of the wind was brought nearly into contact with a cylinder or sphere, the pressure on the latter bodies was augmented by about 20 per cent., owing to the lateral escape of the air being checked. Thus it is possible for the security of a tower or chimney to be impaired by the erection of a building nearly touching it on one side. A number of interesting experiments were made upon the shelter which one surface affords to another. This shelter was found to extend in front to a distance about equal to the breadth of the sheltering surface, and behind to several times that distance. For example, a 9-inch disc being used as the sheltering surface, and a 6-inch disc being placed two inches in front of it, the latter received only two thirds of the pressure it endured if the larger disc was removed, and this reduction in pressure was perceptible, though to a less extent, at all distances up to 9-inches. Behind flat surfaces eddies were found to exist, which caused other surfaces placed behind to be urged forward with considerable force. For example, a 7-inch disc placed behind a 6-inch disc, and 4 inches from it was urged forward with one fifth of the pressure with which it was urged backward when the 9-inch disc was removed. In conclusion it was recommended that 20 lb. per square foot be taken as the maximum wind pressure upon areas of not less than 300 square feet, and 30 lb. for smaller areas in positions of full exposure in the southern and south-eastern parts of Australia; that in more or less sheltered positions these values might be reduced according to judgment, the minimum for extremely sheltered positions being taken as one half the above figures; that the pressure on chimneys, towers, spires, roofs, and other objects be deduced from those on thin plates of equal area by means of the results previously given; and that a factor of safety of two for cases of simple stability, and three where the question is one of strength should be employed.

* Abridgement of paper by Prof. Kernot, Professor of Engineering at the Melbourne University, and published in the *Australasian Builder and Contractors' News.*

PUBLICATIONS.

The R. I. B. A. Kalendar for 1893-94, containing as usual some 300 pages of information concerning the Royal Institute of British Architects, is received.

A SPLENDID CEMENT FOR CELLAR FLOORS.—Numerous methods for making cement floors have been presented; among them the following is said to be the most desirable, producing the best results: Take of coarse gravel or broken stone and sand, 4 parts, and 1 part each of lime and cement. Mix in a shallow box, shovelling over, from end to end, till thoroughly mixed. The sand, gravel and cement, are mixed together dry. The lime is slaked separately and mixed, with just enough mortar to cement it well together. Six or eight inches of the mixture is then put on the bottom, and when well set, another coating put on, consisting of 1 part of cement and 2 of sand. The same process will serve for building a cistern where no brick is intended to be used in bottom or side walls. A cement of 1 part sand, 2 parts ashes and 3 parts clay, mixed with linseed oil, spread over a base of concrete just described, makes a surface very hard and durable and smooth, and said to resist the weather, almost, if not quite as well, as marble.

SANITATION AND HEATING

SCHEMING CONTRACTORS.

Editor CANADIAN ARCHITECT AND BUILDER.

SIR,—As manufacturers of heating apparatus in Canada, we have found for some time past that a considerable difference exists between many contractors throughout the country in the figures that are given for installation of heating plant. We have frequently given the subject considerable thought and have tried to ascertain how it was that such a difference existed between tenders when the architect's specifications stated in detail exactly what quantity of surface was required, and the class of work that was to be done. During the past year in working very quietly to get at the bottom of the matter, we have found that much blame must be laid at the door of the architects, inasmuch as they call for certain goods in their specifications, ask for the work to be done upon a certain line, and then allow the contractors to skimp the work and put in only 75 feet of radiation where 100 feet was originally specified, and the result of this is that Jones who figured on a certain job at $1,000 is left out in the cold because Smith takes the same contract for $750.

We have before our notice to-day a case in which a steam job has been figured on. The architect's specification was handed out to the contractors A and B. A figures on the job and specifies 1724 square feet of radiating surface, and B 1256 square feet of radiating surface. Still the architect lets the contract to B who is short 468 feet of surface on a small job, and A loses the contract feeling that his friend B buys goods considerably less than he does.

We think that it is nearly time that the architects of this Dominion should insist upon the proper quantity of heating surface being put in buildings; as there are to-day in our estimation a very great number of heating engineers who skimp their work at every opportunity. We could give volumes of reports of work of this kind that has come before our notice, but think that this may be sufficient to direct the attention of architects to the practice and bring about more equitable conditions in the heating trade.

"ZERO."

A METHOD OF CELLAR VENTILATION.

A plan by which a cellar may be thoroughly ventilated has recently been worked out by a heating engineer in an American city. The design was made for a billiard saloon in a large cellar situated beneath a restaurant. In this scheme air is taken in through areas in the rear of the cellar, and is to be forced through galvanized iron ducts extending entirely around the bottom of the basement room under a row of chairs provided for spectators, which are ranged round the apartment.

The lower part of this duct—that is to say, that part which lies on the floor of the basement—is provided with openings that deliver the air forced in through corresponding openings through the floor into the cellar below, where, in winter, it is moderately warmed by passing it through box coils, whence it passes through distributing ducts arranged under the floor to numerous registers, arranged around the room, and opening just above the platform for chairs that entirely conceal the main duct. The plenum is obtained by the use of a blower driven by a gas engine placed in the cellar below; but this may possibly be supplanted by an electric engine when the instalment is erected.

SHAVINGS.

New buildings to the value of $140,000 were erected during the past year at Regina, N. W. T.

Much regret is expressed at the failure of Mr. Samuel Swanton, who has been in business in Toronto as a contractor for a quarter of a century.

Among the new books recently added to the Toronto Public Library collection, is one by W. A. S. Benson, on "Elements of Handicraft and Design."

The Manchester ship canal is to be opened for traffic on the first of the New Year, and it is said that a Nova Scotia vessel laden with lumber will be the first to pass through.

One of the oldest and most handsome houses in the city of St. John, N. B., erected on Waterloo street by the late Mr. Carvell in 1864, at a cost of $45,000, was totally destroyed by fire a fortnight ago.

In a recent test case, the validity of the by-law passed by the City Council of Toronto making it compulsory on contractors for city works to pay their employees a minimum wage of 15 cents per hour, was upheld.

The jubilee of the erection on John street, Toronto, of St. George's Church, was celebrated a few days ago, on which occasion there were exhibited the church seal, the original subscription book, a manuscript history of the church, and the silver trowel used by Bishop Strachan in consecrating the church on the 19th of August, 1844.

The General Hospital Board of the City of Kingston has accepted at the hands of Archbishop Cleary, a statue in memory of the Irish emigrants who died at Kingston during the plague of 1847. The statue, which represents a life size figure of an angel, was cut in Italy from Carrara marble. The pedestal will be of Sutherland Falls marble.

DECORATION AND FURNITURE

THE SELECTION OF WALL PAPER.

IN the selection of wall paper the first thing to be taken into consideration is, of course, the purpose for which the papered room is to be used. The selection of paper in that regard depends says *Painting and Decorating*, mainly on the taste of the buyer. But there is another consideration which does not altogether depend on taste, but has to follow certain rules and laws, and this is the amount of light which a room receives. With a room which receives only a moderate amount of light it will be necessary to paper the walls with a light wallpaper, while a room which receives a strong light should be papered the reverse. The next thing to be taken into consideration is the combination of colors, when all the doors of the connecting apartments are opened. It is a main point to have such a combination of different wallpapers, that a whole line of rooms make a harmonious and artistic appearance. The following will make pleasing combinations: Brown-red and olive green, red and green, blue and grey or brown, violet and yellow, but poor and displeasing effects will result if such combinations are used as yellow next to green, violet next to blue, or green next to blue. The same law applies to the selection of furniture stuff, and also in curtains and hangings. Harmony in form and color should not only rule in the single apartment, but the different rooms should form an artistic combination, and this can be effected even with the plainest of furnishing.

Now, it is too frequently a fact, and one which practical paperhangers and decorators will sustain, that in many of the finest houses, where, in regard to furniture and other decorations, the greatest luxury is to be found, hardly any attention is paid to an artistic and harmonious papering and decorating of the walls. There is missing the interest and right understanding of the decorative art. Therefore it is best to employ an experienced decorator and paperhanger and trust to his ability and integrity, until one is enabled through study of decorations and the decorative art to make all needed arrangements personally. It must never be forgotten that it is mainly through the decorations of the walls that the room derives its particular character, be this harmonious, enlivening, sombre or peaceful. It is through the decorations of the walls that the visitor is enabled to form an opinion as to the good or bad taste of the owner.

WROUGHT IRON WORK.

SPEAKING of art work in wrought iron the *Trefoil* remarks: Wrought iron for every purpose is now becoming very popular. It is used for grilles over the door, in the vestibule, for railings and balconies, etc., and wherever found seems to carry with it a recommendation of its own appropriateness.

The dull and yet lustrous color given to iron by the Bower-Barff process is peculiarly quiet and effective, and harmonizes particularly well with both wood and stone.

That the iron is practically rustless, and does not have to be cleaned with that scrupulous and constant care that brass work requires, recommends its use the more, while the artistic merit of grilles now made speaks highly for the taste of the market that requires such work, and stand in strange contrast to the barren lack of even an attempt at any effect whatever in the cast iron models of the past.

The annual Exhibition of the Toronto Art Students' League will open on the 18th inst., and continue until the 23rd inst., in the League rooms, Imperial Bank Building. A souvenir calendar containing poems by Canadian writers and illustrated by members of the League, is to be issued as was done last year.

Mr. Sandford Fleming, C.M.G., is endeavoring to bring about the establishment of a National Gallery of Historic Pictures, and has offered to subscribe a liberal amount annually for ten years for this object, provided there is the prospect that by similar contributions the sum required can be raised within that period.

Mr. Joseph Powell, architect, of Hamilton, is being mentioned as likely to be chosen as a candidate in the approaching election in Haldimand to represent the McCarthy party.

The report of a novel incident comes to us from Ridgeway, Ont. A resident of that town, Mr. Andrew Benner, recently purchased a farm in the locality, and proceeded to make alterations and repairs in the old farm house. Instead of handing the work over to a contractor, he engaged carpenters and acted in the capacity of superintendent of works. While thus engaged he discovered securely hidden away behind the plaster, two well filled canvas bags, containing some $7,000 in gold. The existence of this large amount of money in such an unexpected place is accounted for by the fact that a former owner of the house had thus secreted his wealth with the purpose of keeping it out of the hands of a spendthrift son, and being one day suddenly stricken with appoplexy, passed away without making known the location of the money. Since then the farm is said to have passed through the hands of several owners before being purchased by Mr. Benner, the lucky discoverer of the money.

THE ART OF SUCCESSFUL ADVERTISING.

By ERNEST H. HEINRICHS.

Advertising has become generally recognized as a necessary and important adjunct to every business, trade, profession and mercantile or commercial enterprise. The cobbler advertises his handiwork on the window-ledge; the grocer puts his best stock of vegetables on the sidewalk; the clothier, the dry-goods man and the furniture dealer fill the pages of the newspapers; the actor seeks to attract the attention of the public in flaming posters, and the manufacturer advertises his specialties in the trade papers and magazines. The time worn axiom that good goods do not need advertising is now relegated into the deepest recesses of the business man's vault containing memories of the past, and is brought out only to serve as a dampener upon a two persevering advertising solicitor. In this age of keen competition, it is not likely that any man will have a purchaser for his goods simply because they have the characteristic of excellence. He must promulgate their distinctive advantages or their superiority.

To do this successfully, he must advertise. There are as many ways of advertising as there are roads leading to Rome, and the question is how to find the right one.

To the writer it seems that the first point to be considered is, how much money will the capital of the business to be advertised permit to be used for this purpose? This point, once disposed of, will immediately suggest another one,—how may this sum be expended to the best advantage, or, how can the business be advertised most effectually with this stipulated sum.

The thorough sturdy of these points is of the utmost importance. There must be method pursued in the manner of advertising, if it is to be profitable, else there will be absolute failure. One who decides to embark in any enterprise invariably makes it his first business to find out how much it will cost him to make a start. The same principle applies to advertising. It is a business in itself, the management of which requires the greatest care and attention.

Some people say that they give the papers an advertisement occasionally just to get on the good side of them; others, that they give some man from the papers an advertisement, because he is a "jolly, good fellow." In fact, one gentleman remarked to the writer some time ago that "there is a good deal of sentiment connected with advertising!" Now there is much truth in what this gentleman said, and more is the pity. It is this kind of advertising which is dangerous, inasmuch as it reflects upon advertising as a legitimate business, because it deteriorates to a form of bribery, and it disheartens as well as disgusts both the reputable publisher and the honest advertiser.

Having decided how much money may be spent in advertising, the next question is, how and where is it to be done? To settle this question is very difficult, for the reason that the mediums for advertising are legion. Many old advertisers believe that advertising by circular letter affords the surest and best way to reach a customer. They argue that if they send out a stamped envelope with a type-written page or two of matter inside, the recipient will surely read these pages. Then there are others, who are not particular about having the matter even type-written; they are satisfied to get up an elegant advertisement, have a printer strike off as many copies as they have customers on their books, and then they send these circulars to their customers. Again, there are those who now and again get up a catalogue, in which are set forth descriptions in general and in detail of everything they sell, and they send these catalogues wherever they hope to catch a probable purchaser. Then there are firms who rely entirely upon their agents and representatives to advertise their goods by word of mouth. Most advertisers, however, consider all these methods auxiliary; they help a little, but they do not do much good alone. It may be safely asserted that newspapers, magazines, and trade papers, are now recognized as the standard advertising mediums.

The object of advertising is to make certain statements known to the public at large. Hence the more people see the advertisement the more thoroughly does it fulfil its mission. Of course this opinion may be questioned by the advertiser of specialties, who desires to reach a certain class of people only, but this statement is meant to apply to advertising in general, though it would require merely a slight modification to apply to all cases. Nevertheless, one fact, borne out by the most successful advertisers in America and in Europe, is that what is broadly understood by newspaper advertising is the best and cheapest advertising that can be had. The term "newspaper" includes of course periodicals of every class.

In choosing a publication some people have very peculiar ideas; if they see a paper with a large number of advertising pages, they take it for granted that an advertisement in such a paper means money thrown away, because the advertisement will be crowded out of sight. This is a mistake. The best papers, as a rule, have the largest amount of advertising; hence they must be the best advertising mediums. The best papers are apt to be the most widely read, so that advertisements in them must of necessity become widely circulated, which is the great object of advertising. To this reasoning it may be replied that it does not follow, that because an advertisement is circulated among ten thousand people, ten thousand people will read it. Certainly not, but an advertisement circulated among ten thousand people stands a better chance of being read ten thousand times than an advertisement circulated among only five thousand people. Apart from this deduction of simple logic it must not be forgotten that advertisements are read with as much interest as any other portion of a newspaper. This may not always have been so, but it is nevertheless true to-day. It may be that the busy man will carelessly pass over the advertising columns of the daily newspaper, but the housewife will read them twice and thus make up for his neglect. But take the popular magazines of to-day, the advertising pages of which are truly remarkable, not alone in their appearance, but also as regards their contents. Does any one dare to assert that an advertisement placed anywhere in these pages is a lost investment? The advertising pages of these periodicals represent from month to month the most striking reflection of the commercial, the industrial, and the financial, as well as the intellectual, progress of this country, and the intelligent readers of these publications are just as much interested in the perusal of the advertising pages as of the essays, stories and other features.

A business man, having decided to advertise, and having set apart a certain sum for this purpose, should go to that publication which is read by the largest number of people interested in his business, which most probably will be that publication which has the most advertisements and pays the most attention to the manner of setting up and arranging the advertising pages.

The advertising rates in the best publications are very low. Many people, and even some advertisers of experience, will doubt this statement, but that does not detract from its correctness. The trouble is we expect too much from an advertisement. It must not be supposed that a single advertisement, for which perhaps $50 has been paid, is going to fill a store with customers for a year to come, thus bringing a profit on the investment of probably ten hundred per cent. Most people are satisfied, if they make one hundred per cent. on their invested capital, and everybody should commend them for their modesty. Why, then, should a larger profit be expected from an advertisement than from any other investment?

Advertising once commenced, must be kept up, and if conducted with the same thoughtfulness, the same care, and the same business methods exercised in any other enterprise, an advertisement will always prove a profitable investment.

There is one other feature connected with the business of advertising, which, although the writer has so far not made mention of it, is nevertheless of no less importance than the others. This is the manner of composing an advertisement. It is impossible to form any set of standard rules as a guide for the composition of advertisements, except in so far as that they should in all cases be so worded that they will at once attract attention and be read. To be brief, concise, clear, and to the point in writing an advertisement is undoubtedly commendable, and a plain statement is always more liable to carry weight with the reader than a long string of ambiguous phrases, which have no defined meaning when analyzed.—*Engineering Magazine.*

HOW TO USE CEMENT.

The following general rules referring to the practical use of cement are reprinted from the *National Building Register*:

QUALITY OF SAND—The sand should be clean, sharp and coarse. When the sand is mixed with loam the mortar will set comparatively slow, and the work will be comparatively weak. Fine sand, and especially water-worn sand, delays the setting of the cement, and deteriorates strength. Damp sand should be mixed thoroughly and uniformly together, when both are dry, and no water should be applied until immediately before the mortar is wanted for use.

PROPORTION OF SAND—The larger the proportion of cement the stronger the work. One part of good cement to two parts sand is allowable for ordinary work; but for cisterns, cellars, and work requiring special care, half and half is the better proportion. For floors, the cement should be increased toward the surface.

WATER IN CONCRETE—Use no more water in cement than absolutely necessary. Cement requires but a very small quantity of water in crystallizing. Merely dampening the material gives the best results. Any water in excess necessarily evaporates and leaves the hardened cement comparatively weak and porous.

CONCRETE IN WATER—Whenever concrete is used under water, care must be taken that the water is still. So say all English and American authorities. In laying cellar floors, or constructing cisterns or similar work, care must be taken to avoid *pressure of exterior water*. Cement will not crystallize when disturbed by the force of currents, or pressure of water, but will resist currents and pressure after hardening only. In still water good cement will harden quicker than in air, and when kept in water will be stronger than when kept in air. Cements which harden especially quick in air are usually slow or worthless in water.

HOW TO PUT DOWN CONCRETE—When strong work is wanted, for cellar floors and all similar work, the concrete should be dampened and tamped down to place, with the back of a spade, or better, with the end of a plank or rammer; then finished off with a trowel, thus levelling and compacting the work. Only persons ignorant of the business will lay a floor or walk with soft cement mortar. All artificial stone is made in a similar way to that described, and, when set, is strong and hard as stone.

DELAY IN USE—Do not permit the mortar to exhaust its setting properties by delaying its use when ready. Inferior cements only will remain standing in the mortar-bed any length of time without serious injury.

STONE AND BRICK WORK—In buildings constructed of stone or brick, the best protection from dampness and decay, and also from the danger of cyclones, is a mortar of cement and coarse sand. The extra cost is inconsiderable, and the increased value of the structure very great. Chimneys laid in this manner never blow down, and cellars whose foundations are thus laid are always free from atmospheric moisture. Cement may also be mixed with lime mortar for plastering and other purposes, to great advantage.

EFFECT OF FROST AND COLD—At a temperature less than 60 degrees Fahrenheit, all good cement sets slowly, though surely, but if allowed to freeze its value is seriously impaired. In cold weather or cold water do not fear to wait for your concrete to crystallize.

DAMAGE FROM MOISTURE—Good cement is not injured by age, if carefully preserved from moisture. Lumps in bags or barrels of cement are caused by exposure to moisture. They prove the originally good quality of the cement.

LEGAL DECISIONS.

Mr. Justice Ouimet, of Montreal, in the case of Beaulieu vs. Brouillet, decided a point of much interest to architects. The action was taken to recover an amount alleged to be due under a written building contract for certain work done, and an additional sum for extras. The plaintiff had endeavored to produce evidence to establish the value of these extras: but the defendant objected, and the objection has been maintained. It is held that an architect can only claim for work done under written contract, and in the absence of a written agreement or an admission under oath by the person for whom the work was done as to the value of the extra work, no claim can be entertained. In the present case the plaintiff had neglected to have a written agreement drawn up before commencing the extra work.

UNIFORM FORM OF PROPOSAL.

As the result of joint deliberation on the part of a Committee of the Builders' and Traders' Exchange of Milwaukee, and the Architects of that city, the use in future of the following uniform form of proposal is recommended:

Milwaukee, Wis. .....189..

NOTICE.

THIS BID IS GIVEN UPON THE FOLLOWING EXPRESS CONDITIONS, VIZ:

1. All bids are to be made known upon the awarding of contract or within five (5) days of the opening of the bids.

2. It is expressly agreed by the bidder that he will make contract for the price named within ten (10) days from the specified time set for receiving bids.

3. Where the owner or agent demands a bond from the contractor, the contractor shall be entitled to a bond from the owner or agent for the prompt payment of the sums named in the contract, and for the faithful performance of such other conditions and terms as may be set forth in said contract.

4. The contractor shall be entitled to 5 per cent. on all materials furnished by the architect, owner or agent upon which materials the undersigned has bid and contracted for.

To.....Architects:

The undersigned propose to furnish all the material and to perform all the labor required for the.....work of a.....to be built for Mr.....in accordance with the plans and specifications for the sum of

.....*Dollars* ($.....)

USEFUL HINTS.

A yellowish-brown luminous paint is obtained from 48 parts auripigment and 34 parts luminous calcium sulphide.

One-fifth more siding and flooring is needed than the number of square feet of surface to be covered, because of the lap in the siding and machinery.

The ends of all timbers, and especially of large beams should be free (for it is through the ends that moisture chiefly evaporates). They should on no account be embedded in mortar. Beams may appear sound externally and be rotten within, for the outside, being in contact with the air, becomes dryer than the interior. It is well, therefore, to saw and reverse all large scantling.

PLASTER USED FOR FLOORING.—It is stated by an exchange that French builders, who have carried the art of hardening plaster to where it is used for flooring, either in place of wood or tile, employ for this purpose six parts of good quality of plaster intimately mixed with one part of freshly slacked white lime finely sifted. The mixture as thus composed is laid down in as quick time as possible, care being taken that the trowel is not used upon the surface for too long a time; after this the floor is allowed to become very dry, and is subsequently saturated in the most thorough manner with sulphate of iron or zinc, the iron giving the strongest surface, its resistance to breaking being found to be 20 times the strength of ordinary plaster. It appears that with sulphate of zinc the floors remain white, while when iron is used it becomes the color of rusted iron; but if linseed oil, boiled with litharge, be applied to the surface, it becomes of an attractive mahogany color, this being especially the case if a coat of copal varnish is added.

To test the purity of white lead is not a difficult matter, and does not necessitate a knowledge of chemistry. The simplest way is to crush a small quantity of dry lead on a sheet of paper, fold it, and holding it over a plate or saucer, set fire to it. The heat will change the white lead, if pure, into metallic lead, which will drop in the form of shining grains; if it is adulterated, no indications of metal will be apparent. Another method is to spread a thick layer of the lead over a very thin pine board. On burning it, the metallic particles will be visible only when the lead is pure. A more accurate method than either is that of using charcoal and blow-pipe. Take a flat piece of charcoal about three inches long, one inch wide, and one-fourth of an inch thick, hollow out a small cavity and place within it a piece of the suspected lead about the size of a pea. Then take a blow-pipe and a spirit lamp, and direct the flame on the lead; keep up a continual and steady blowing, and allow the blue part of the flame to reach the lead. In a couple of minutes the lead, if pure, will be reduced to a small shining piece of pure metallic lead; if it be adulterated, no amount of blowing will produce the same result. A tobacco pipe (common clay), having a small stem, may, at a pinch, be used as a blowpipe.

The work of rebuilding the St. Johns Stone Chinaware Company's factory at St. Johns, Que., is actively progressing.

At Guelph, during 1893, buildings were erected to the value of $100,000, and on other improvements there was expended $10,000.

Resin is utilized for making the varnish used by Venetian blind manufacturers for painting their blinds. This varnish is mixed with the desired color, mostly green, and when painted gives a hard gloss enamel surface.

NEW YEAR NUMBER - PRICE, 35 CENTS.

CANADIAN ARCHITECT AND BUILDER.

VOL. VII.—No. 1. JANUARY, 1894 { PRICE 20 CENTS $2.00 PER YEAR.

—THE—
CANADIAN ARCHITECT AND BUILDER,
A Monthly Journal of Modern Constructive Methods.
(With a Weekly Intermediate Edition—The CANADIAN CONTRACT RECORD),
PUBLISHED ON THE THIRD THURSDAY IN EACH MONTH IN THE INTEREST OF
ARCHITECTS, CIVIL AND SANITARY ENGINEERS, PLUMBERS, DECORATORS, BUILDERS, CONTRACTORS, AND MANUFACTURERS OF AND DEALERS IN BUILDING MATERIALS AND APPLIANCES.

C. H. MORTIMER, Publisher.
Confederation Life Building, - TORONTO, CANADA.
Telephone 2362.
64 TEMPLE BUILDING, - MONTREAL.
Bell Telephone 2290.

SUBSCRIPTIONS.
The CANADIAN ARCHITECT AND BUILDER will be mailed to any address in Canada or the United States for $2.00 per year. The price to subscribers in foreign countries, is $2.50. Subscriptions are payable in advance. The paper will be discontinued at expiration of term paid for, if so stipulated by the subscriber; but where no such understanding exists, will be continued until instructions to discontinue are received and all arrearages paid.

ADVERTISEMENTS.
Prices for advertising sent promptly on application. Orders for advertising should reach the office of publication not later than the 10th day of the month, and changes of advertisements not later than the 5th day of the month.

EDITOR'S ANNOUNCEMENTS.
Contributions of technical value to the persons in whose interests this journal is published, are cordially invited. Subscribers are also requested to forward newspaper clippings or written items of interest from their respective localities.

The "Canadian Architect and Builder" is the official paper of the Architectural Associations of Ontario and Quebec.

Subscribers who may change their address should give prompt notice of same. In doing so, give both old and new address. Notify the publisher of any irregularity in delivery of paper.

ONTARIO ASSOCIATION OF ARCHITECTS.

OFFICERS FOR 1893.

PRESIDENT	D. B. DICK, Toronto.
1ST VICE-PRESIDENT	KING ARNOLDI, Ottawa.
2ND VICE-PRESIDENT	JOHN E. BELCHER, Peterboro'.
TREASURER	EDMUND BURKE, Toronto.

COUNCIL:

DAVID EWART	Ottawa.
S. G. CURRY	Toronto.
S. H. TOWNSEND	Toronto.
FRANK DARLING,	Toronto.
W. A. EDWARDS	Hamilton.

REGISTRAR AND LIBRARIAN:
W. A. LANGTON - Canada Life Building, Toronto.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.

OFFICERS FOR 1894.

PRESIDENT	J. NELSON, Montreal.
1ST VICE-PRESIDENT	CHAS. BAILLAIRGÉ, Quebec.
2ND VICE-PRESIDENT	A. C. HUTCHISON, Montreal.
SECRETARY	JOSEPH HAYNES, Montreal.
TREASURER	J. Z. RESTHER, Montreal.

COUNCIL:

A. T. TAYLOR, F.R.I.B.A., R.C.A.	Montreal.
A. GENDRON,	Montreal.
J. B. BERTRAND	Quebec.
ERIC MANN	Montreal.
J. VENNE	Montreal.
G. TANGUAY	Quebec.

AUDITORS—THEO. DAOUST, J. F. PEACHY.

TORONTO BUILDERS' EXCHANGE.

BOARD OF DIRECTORS:

WM. PEARS, President.	J. LISTER NICHOLLS.
WM. PARK, 1st Vice-President.	WM. BOOTH.
GEO. OAKLEY, 2nd Vice-President.	JAS. ISAAC.
DAVID WILLIAMS, Treasurer.	JOHN LOGAN.
WM. J. HILL.	JAS. THOMSON
JOHN ALDRIDGE.	H. MARTIN.
JAS. CRANG.	

JOHN L. PHILLIPS, Secretary.

AT the time of going to press the members of the Ontario Association of Architects are meeting in annual convention in the School of Practical Science, Toronto. A full report of the proceedings will be published in the CANADIAN ARCHITECT AND BUILDER for February.

1894.

THE commencement of a new year, which will be the seventh in the life of this Journal, prompts a few remarks of a personal character, and concerning the professional and business interests with which we stand identified.

IT will be observed that in this first number of the new year a departure has been made from our usual practice of publishing illustrations of exclusively Canadian buildings. Having been repeatedly requested to reproduce occasionally foreign subjects, it was decided to give up the present number to illustrations of work of this character, and the cover design, for which we are indebted to Mr. Ernest Wilby, was worked out in harmony with this idea. It is our purpose in future to reproduce from time to time suchspecimens of the work of foreign architects as it is hoped will prove interesting and instructive to our readers.

Regarding the CANADIAN ARCHITECT AND BUILDER, it can be said that despite some adverse influences, it continues to make steady progress. Additions to the number of its subscribers throughout Canada, and especially the towns and cities of the Northwest, have of late been gratifyingly large. As an index to the esteem in which the ARCHITECT AND BUILDER is held by some of its subscribers, we quote from the letter of an architect in a western Ontario city as follows: "I take all the best architectural publications in the States—six in number—and yours—and not considering price, I think yours the best of the lot for everyday practical work, and for good solid reading." The writer of this letter adds, "Can you suggest anything I can do to help you—if so, it shall be done." It would enhance not a little the interest and prosperity of the Journal, if every architect, builder and contractor who is a subscriber, would evince similar anxiety to individually assist its development. To those who have been negligent in this particular, the present affords a good opportunity to turn over a new leaf.

A strong effort will be put forth to give to the ARCHITECT AND BUILDER during 1894 a greater interest than it has ever had before, and without lessening its value to architects, to make it the source of information of a useful character to master builders and contractors. The co-operation of our readers is invited. Let us know what class of information is most required and we will endeavor to supply it. Especially do we invite requests for information on problems arising out of construction work of any kind; in such cases an earnest effort will be made to throw light on the difficulty. If knowledge of new and improved methods has been acquired let us know about it so that our readers may share the advantage. There has in the past been too little in the nature of exchange of experiences on this line. Let us have more of it in the future, and the result will be beneficial to everybody. Let no reader think he "knows it all"—he doesn't. If he will give others the benefit of what he does know he can depend on receiving equally valuable information in return.

In the advertisement pages of the ARCHITECT AND BUILDER are represented the leading manufacturers and dealers in building materials and appliances. The attention of architects and

builders is constantly being drawn in these pages to improvement in materials, and no progressive architect or builder should fail to examine these announcements with the same degree of attention which he bestows on any other department of the Journal. It is the wide-awake, progressive manufacturer and dealer who advertises, and who is able to place at the disposal of architects and builders the newest and most improved materials, and is consequently most deserving of encouragement and patronage. The successful results achieved in modern buildings are due in no small measure to men of this class.

We have made a certain amount of careful enquiry since the opening of the year, in order to gain what knowledge we might regarding the building outlook for 1894, this being always a subject of paramount importance to the many whose interests are largely dependent upon building enterprise. These enquiries indicate that a fairly active season is in prospect, and that taking the country as a whole the volume of building operations in 1894 will equal if not exceed that of last year. If this should prove to be the case there should be little cause for disappointment in view of the world-wide depression which at present exists. It must be remembered that most Canadian cities with the exception of Toronto were more than usually active in building enterprise last year. This is especially true of Montreal, London, Ottawa and Winnipeg. In Toronto the existence of well-known local causes operated to check development in this line; and yet even in Toronto a considerable amount of the best class of building was done, and all are agreed that so far as that city is concerned if no improvement may be expected as compared with last season, there will be no retrogression. The remodelling of existing buildings which began a year or two ago may be expected to continue for some time to come. This applies not only to buildings used for business purposes, but also to central residential properties. It is learned that there is a brisk demand for modern residences in central localities, and that as fast as houses are modernized they are tenanted. If this fact were impressed on the attention of owners of central property, much of which is now unremunerative because of the lack of accommodation afforded by old style houses, extensive improvements would doubtless follow.

There is another direction in which improvement is demanded and which would tend to enhance considerably building activity in Toronto during the coming season. There is urgent need, as was pointed out by the Mayor in his inaugural address, for large additions to the school accommodation throughout the city. At present the School Board are obliged to rent upwards of thirty rooms to provide for the large number of pupils who for lack of room cannot be admitted to the school buildings. For this temporary accommodation, which is necessarily defective, the School Board pays a rental of about $7,000 per year. This amount capitalized at 4 per cent. would pay interest on $175,000. It is estimated that the additional accommodation required could be provided by building additions to the present school buildings at a cost of $75,000 to $80,000. The interest on this expenditure would be $3,000 to $3,500, or half the sum which must now be paid as rent for inferior accommodation. Thus by enlarging the present schools a saving of upwards of $3,000 per year might be effected, more satisfactory accommodation provided, and a large sum of money expended which would assist in tiding builders and builders' supply houses over the brief period which will elapse before a decided improvement in conditions shall take place. There is additional reason for proceeding at once with this work in the fact that there is never likely to come a time when it can be carried out at less cost. We hope that the City Council will take cognizance of these facts, and when the estimates of the School Board come up for consideration, vote the amount required to enlarge the schools.

Outside of Toronto indications of considerable activity are already apparent, and as above stated, we believe the season will develop satisfactorily. A certain number of persons, including architects and supply firms, appear to have become suddenly discouraged, and are doing little else than putting on long faces and predicting that things are going to the "bow-wows." Such persons are doing not a little to retard the improved conditions which all are looking for and which there is no reason to suppose will be much longer delayed. Let everybody put a cheerful courage on, and do what is possible to inspire confidence in the future; in this way "good times" will the sooner be brought about. There is cause for the greatest encouragement in the knowledge of the fact that while Canada is less prosperous than at some former periods in her history, she is to-day experiencing in a lesser degree than any other country on the face of the globe the existing commercial depression, and as a consequence will be among the first of the nations to feel the benefit of the rising tide of returning prosperity. Let us stop croaking and go to work to make the best of the situation, which after all, isn't half so bad as some have pictured it.

WE are much gratified by the interest manifested in our students' competition for a Town House, the result of which is announced in another part of this paper. Fifteen designs in all were received in this competition, representing the work of students in the provinces of Ontario, Quebec and British Columbia. The interest which has thus been shown shall encourage us to announce other competitions from time to time in the future.

CANADIAN SOCIETY OF CIVIL ENGINEERS.

The eigth annual meeting of the above Society took place in Montreal on the 10 and 11th inst. There was a good attendance of members. The chair was occupied by the President, Mr. E. P. Hannaford.

The subject of organizing the Society into a close corporation, was reported on by a committee, the carrying into effect of the proposal being supported by Mr. Alan Macdougall, of Toronto. It was decided, however, that no present action should be taken.

The treasurer's report showed a very satisfactory state of the finances, and that in all respects the Society was in a flourishing condition.

By invitation of the Montreal Street Railway Management an interesting visit was made to the Company's new power station, and on the evening of the second day the annual dinner was held at the Windsor, the occasion proving to be most enjoyable.

The election of officers resulted as follows: President, P. Alexander Peterson; Vice-Presidents, H. Wallis, P. W. St. George, Montreal, and Alan Macdougall, Toronto; Secretary, Prof. McLeod; Treasurer, K. W. Blackwell; Librarian, W. McNab.

TORONTO BUILDERS' EXCHANGE.

The annual meeting of the Builders' Exchange of Toronto was held in the rooms of the Association, 8 Victoria st., on Monday, January 15th, at 3.30 p. m., the President, Wm. Pears, presiding.

The following were present; Wm. Pears, Jas. Crang, Jno. Aldridge, Mr. Tasker, (rep. the Don Brick Co.) J. Vokes, H. Martin, J. Thompson, Mr. Hewitt, Jr., T. Cannon, Sr., T. Cannon, Jr., Jno. Lucas, Geo. Wright, J. Bedford, Edw. Gearing, Ben. Brick, Jno. Maloney, Jno. Barnard, W. Page, F. B. Lockwood, Jno. Vick, C. S. Boon, Jno. Russell, Geo. Oakley, Wm. Park, Wickett Bros., Curtis & Rowe, Jas. Priestley, Isaac Price, Bayliss & McCurdy and Thos. Aikenhead.

The Treasurer's report, attested by the auditors, showed the finances to be in a satisfactory condition. The Secretary's report showed the membership to comprize the names of 120 firms representing all branches of the building trade and the supply business. The directors report was discussed with much interest. The Lien Law Committee were praised for the satisfactory work accomplished in connection with the amendment to the Lien Act. The president in commenting upon the bill, expressed his opinion that the amendments would tend to put the building trade upon a more satisfactory foundation, and that rash speculation in building would be less likely to occur in the future.

The following officers were elected for 1894:—Wm. Pears, President, re-elected, unanimously; 1st Vice-President, Wm. Park; 2nd Vice-President, Geo. Oakley, re-elected; Treasurer, David Williams, re-elected. The following were elected upon the Board of Directors: Jno. Aldridge, Jas. Thomson, Wm. Booth, Jas. Crang, H. Martin. In addition to the above the Board will be supplemented by one representative from each Trade Section of the Exchange. The auditors for 1894 are Messrs. Geo. Clay and Frederic Holmes

The President-elect thanked the Exchange for the honor of his re-election, and also congratulated the members upon the satisfactory progress of the Exchange, in spite of dull times.

ILLUSTRATIONS.

C. A. & B. COMPETITION FOR A TOWN HOUSE—DESIGN BY "IGNORAMUS" (MR. J. EUGENE PAYETTE, MONTREAL) AWARDED FIRST POSITION.

"BITS FROM MY SKETCH BOOK"—BY EUSTACE G. BIRD.

CERTOSA DI PAVIA, FINESTA SULLA, FACCIATA DELLA CHIESA, ITALY.

TOWERS AND STEEPLES—SIR CHRISTOPHER WREN, ARCHITECT.—(REPRODUCED FROM ORIGINAL DRAWINGS BY MR. A. T. TAYLOR, F.R.I.B.A., MONTREAL).

CHATEAU D'AZAY-LE-RIDEAU, FRANCE.

THE WEST END OF NAVE, WELLS' CATHEDRAL.—FROM A DRAWING BY MR. E. WILBY.

The portion of nave shown in this view dates from the earlier part of the 13th Century. The strong Romanesque feeling running through the whole design is quite exceptional in a building of so late a date. It may be seen in the form of the clustered piers, the profile of the arch mouldings, in the continuous mould to triforium arcade, and in the square or octagonal abaci to capitals in place of the more usual circular Early English.

UPPER PART OF MAGDALEN TOWER, MAGDALEN COLLEGE, OXFORD.

"Magadalen College" said Lady Macaulay, "is one of the most remarkable of our academical institutions. Its graceful tower catches afar off the eye of the traveller who comes by road from London. As he approaches he finds that this tower rises from an embattled pile, low and irregular, yet singularly venerable, which, embowered in verdure, overhangs the sluggish waters of the Cherwell."

The window tracery and other carved work has been carefully restored and a new stone figure of St. Mary placed in the middle pinnacle on the eastern side. The tower is 150 feet high, and contains a "ring" of ten bells. It was built in 1492-1507 A.D; and for simplicity of design and graceful proportions it is unequalled in England.

EUSTACE G. BIRD.

"CANADIAN ARCHITECT AND BUILDER" COMPETITION FOR A TOWN HOUSE.

THE best designs received in this competition have faults which would negative their actual erection without alteration, but there is sufficient merit in them and sufficient evidence of study to fully merit the award of the prizes offered. The three best designs are by "Ignoramus," "Gotham," and "Colonial," the three prizes have been given to them in that order.

"Ignoramus" sends in a design, published in this number, which has the defect of not being essentially a town house, and the further defect of an attic (reached by a stair crossing a window) which, slim as it appears in plan, would be still worse in execution, and it is obvious that he was quite aware of this from the floor lines which he has set against the elevations. But the other floors are good, especially the ground floor, which is very well arranged for comfort and interior effect, and on the whole there is an originality and thought shown.

"Gotham" has a good design also. It is a great question whether it would not be better if turned over so as to get the dining room on the south. The arrangement of the front bedroom is unstudied, and the back stairs rather too close work and too dark for comfort. The style of exterior treatment is very good and simple.

"Colonial" has a very clear drawing. The plan is more complex than those of the first two and has many faults. The main stair is ill planned and could have been right in the same space. The kitchen is too small; the dining room is all doors and windows. The stable is impractical.

The other competitors have been arranged approximately in order but without the same effort at certainty as was made in arranging the relative positions of the first three. The following points with reference to them may be noted:

"Demos," who makes a good fourth, has a rather commonplace plan but an elevation showing considerable merit and feeling for brickwork.

"Peck" has some excellent points, and is none the worse for not having very salient features. All is in fairly good quiet taste. He should black his walls in plan for reproduction on a reduced scale.

"Module" has not fulfilled the conditions. There is not enough room left on the lot for light on one side and a driveway on the other. The floor plan thus gets a roominess to which it is not entitled. The elevation shows understanding of colonial work.

"Hasty"—The kitchen is too small. The pantry is only a bit of passage. The dining room is 12'6" wide, has a mantel on one side and a radiator on the other. This interference with the passageway on both sides would be a serious inconvenience in so narrow a room. The bedroom floor is not well studied. The exterior is unpretending but not bad.

"1894" has a very good plan, a little ambitious, but without falling into striking defects. The exterior is not pleasing, but is also not commonplace.

"Far" has made an initial mistake in having planned a basement kitchen. In spite of the space thus gained on the ground floor he has not succeeded in giving an impression of space. The elevations show originality, though in a crude stage.

"Scribbler" has a very good straightforward plan, but with all the rooms to the north, and the south occupied by stairs and a long passage. The design is poor.

"Victoria" has a basement kitchen at the extreme front (under the drawing room) and a dining room at the extreme back on a floor above. It would be hard to atone for this to a housekeeper by any other convenience proceeding from this arrangement, and there does not seem to be anything of the kind. The storey thrown over the driveway is a good idea.

"Cosmo"—The elevations (drawn in a scratchy way) are good—much better than the plan, which seems to show inexperience. The stairway is badly placed, right at the front door.

"Gamut," "Jack" and "Enchell" seem hardly up to the competition.

SETTING AND BURNING ROOF TILES.

IN setting plain roofing tiles the first thing to do is to see that the kiln bottom is in proper shape. This should fall from the sides to the center about 1½ inch, that is, it should be 1½ inch lower in the middle than the outer sides; this tends, when the sinking of the goods commences, to bring them together for mutual support. On the other hand, if the kiln bottoms are dead level, the setting is liable to open in firing, and the tiles reel in various directions, causing great waste. In setting plain roof tiles, these should be set in courses, each course covering a certain extent of ground before No. 2 course is set, and not built up in bungs, which is sometimes done. The latter system gives no tie of support; plain tiles in setting should be interlocked; each 10 or 11 tiles, as the case may be, should be set on the header and stretcher principle. This forms another tie to keep from reeling, and every other tile should be reversed, *i.e.*, the plain end of one tile resting against the *nib* of the previous one, leaving a cavity between the tiles for the draught. In setting pin tiles, say 8 or 10 tiles in a bung, divide the number given in equal quantity, and bring them together in a convex form; this gives you heat passage through the centre as well as the angle of the bung, set on the header and stretcher plan, same as the nib tile. Firing should be done with great caution; all through the burning special care should be taken until the fire is clear through, which should be done in a steady and progressive manner.

MOSAICS LAID IN GOLD.

The church of St. Mark, in Vencie, is said to contain the finest mosaics in the world. And, indeed, in not many places will they be found laid in such costly beds and with such extravagant profusion. On the walls, the ceilings and cupolas the tiny bits of rare marble are laid in exquisite designs on a bed of gold. Of these there are over 40,000 square feet of surface, the effect of the colored marble, each individual piece surrounded by its thread of gold, impress the beholder with a sense of grandure and beauty rarely experienced in gazing at the best efforts of the builder's art.

A Michigan paper announces the receipt by a local builder of a large shipment of cedar lumber from Messrs. Geo. Cassidy & Company, Victoria, B. C., and describes the material as follows:—It is absolutely clear, lighter in weight than pine, of beautiful color and texture, and best of all, not more expensive than our best clear dry pine, very little of which is now obtainable at any price. This wood is growing rapidly in public favor for interior finishing, its natural shades and graining, when it is properly filled and oil polished, being equal to the most expensive hardwoods. It also takes the place of baswood and more expensive material for carriage work.

WINNIPEG.

(Correspondence of the CANADIAN ARCHITECT AND BUILDER.)

There is little or no stir in the building line here at present—not even a rumour about an office building, or new opera house. "'Tis strange, 'tis passing strange," for at this time each year we are entertained with graphic descriptions of costly "sky-scrapers" to be erected the following spring—and as for opera houses, they are without number—designed and fitted up in the most improved style, and second to none, here or elsewhere. The newspapers are always "creditably informed" that the "capital" has been subscribed, and that the work will be proceeded with at once, if not sooner. In spring the snow disappears—carrying with it those visions grand, and with them the hopes of the architects, who then dream of what might have been if their clients—the men of ideas—had only succeeded in dazzling the men of dollars, with the prospect of reaping a golden harvest from the investment of the capital required to carry out their ambitious projects.

Some three years since the Y.M.C.A. purchased an excellent site for their new home at the corner of Portage avenue and Smith street, and they have paid off the major portion of the purchase money. Some of the leading men of the city have promised, as soon as the balance is paid, and the property free of encumbrance, to erect thereon an association building designed "up to date," for it has become a recognized fact that it is a benefit, not only to the young men themselves, but also to the community at large—for the former to have a home to which they are ever welcome, and a place of recreation, where they can enjoyably spend their evenings, and improve themselves spiritually, mentally and physically.

The Hudson's Bay Company, under the management of Mr. Chipman, the Commissioner (who took charge about two years ago) are like the bears in the spring time awakening from their lethargy, and shewing evidence of renewed life—making their influence felt throughout Manitoba and the North-West, while their unprofitable branches are being lopped of. The company, octopus like, stretch forth and take possession of new and promising districts, consequently they have to expend a considerable amount each year providing new buildings in which to carry on their ever increasing business. This necessarily stimulates trade in the country, and is a benefit to all.

Winnipeg should congratulate herself that the Hudson's Bay flats, lying between Main street and the Red River, are no longer to remain the eyesore they have hitherto been, for the proprietors (the Hudson's Bay Co.) have decided to turn them into athletic and racing grounds. This is one of the most laudable enterprises ever undertaken here, and will without doubt prove a great boon to the citizens, for the grounds are in the heart of the city, where everyone can go for a day's enjoyment without cost or fatigue. The grading was commenced last autumn, and this year fences, grand stand, stables and other buildings will be erected.

The Provincial Government provided in the estimates for the current year, the sum of $45,000 for the erection of a Normal School building, and last spring they applied to the Dominion Government to grant a portion of the old driving park—fronting on Broadway—for a site for the proposed building. The Dominion Government consented to give the site, but afterwards, at the solicitation of the Winnipeg Cricket Club—who, from some misunderstanding, thought their grounds adjoining, and consequently their game would be seriously interfered with—were the building erected there. The Dominion Government reconsidered the matter and declined to convey the land to the Province. It is to be hoped that "the powers that be" will give the matter their favorable consideration, now that W.C.C. have received light, and find that they were making "a mountain out of a mole hill." This site is one of the finest, if not the finest, for the purpose, being next and opposite the Government buildings and in the centre of the fashionable south end, where parents are willing to pay the additional fee required to permit their children to attend the model classes in connection with the Normal School.

Regret has been expressed that in a progressive city such as this, which can boast of excellent ward schools and colleges, that the Normal School should have no home of its own in which to carry on its important work, and complete the links of the chain of our admirable system of education, because, forsooth, the noble game of cricket must not be interfered with.

When old Fort Garry was removed to make way for the onward march of civilization, the arched stone gateway alone remained. With battlements bleached and walls worn by time and tempest, it stands as an object lesson, reminding the passing beholder of the exciting scenes and stirring times which occurred within its massive portals during the early days when this country—now beginning to blossom as a rose—was known as the "Great Lone Land." Among the many suggestions regarding its preservation, one of the best is, that the city purchase the site on which it stands for a public park, the situation and the fine trees making it an excellent property for the purpose. Another suggestion is for the Provincial Government to remove the gateway, and re erect at the entrance of the grounds of either the Government House or the Legislative buildings, which, if acted upon, would combine sentiment with utility. The Historical and Scientific Society of Winnipeg invited in the autumn subscriptions towards a fund for the restoration of this interesting relic of ages passed away, but unfortunately their invitation was not responded to with the outburst of enthusiasm so common in more sentimental countries. We are a plain practical people and little affected by sentiment, especially at this season when paterfamilias is reminded daily that the coal pile is growing beautifully less, and the weather delightfully colder. Should this famed monument historique, which seems to be "nobody's child," crumble to dust, and be lost to coming generations, a blot will ever rest on the fair name of those in authority, and children yet unborn will rise up and call them—well, not exactly blessed—for their indifference and parsimony in not preserving what will then be known as the lost stones of Fort Garry.

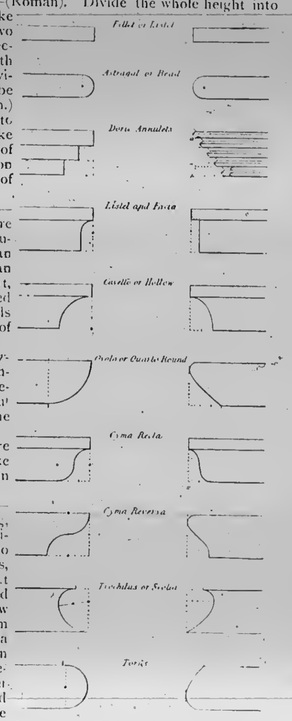
MOULDINGS.

Fillet or Listel right-angled mouldings require no description.

The Astragal or Bead.—To describe this moulding, divide its height into two equal parts, and from the point of division as a centre, describe a semi-circle, which is the contour of the astragal.

Doric Annulets.—The left-hand figure shows the Roman, and the right-hand figure the Grecian form of this building. To describe the latter, proceed thus: Divide the height *b a* into four equal parts, and make the projection equal to three of them. The vertical divisions give the lines of the under side of the annulets, and the height of each annulet, *c*, *c*, is equal to one-fifth of the projection; the upper surface of *c* is at right angles to the lines of slope.

Listel and Fascia.—(Roman). Divide the whole height into four equal parts, make the listel equal to two of these, and its projection equal to two. With the third vertical division as a center, describe a quadrant. (Grecian.)—Divide the height into four equal parts, make the fillet equal to one of them, and its projection equal to three-fourths of its height.



Cavette or Hollow.—In Roman architecture this moulding is a circular quadrant; in Grecian architecture it is an ellipitical quadrant, which may be described by any of the methods given in the first part of the work.

Ogolo or Quarter-round—This is a convex moulding, the reverse of the cavetto, but described in the same manner.

Cyma Recta.—A curve of double curvature, like former, and formed in same manner.

Trochilus of Scotia.—A hollow moulding, which, in Roman architecture is formed of two unequal circular arcs, thus: Divide the height into ten equal parts, and at the sixth division draw a horizontal line. From the seventh division as a center, and with seven divisions as radius, describe from the lower part of the moulding and arc, cutting the above horizontal line, and join the center and the point of intersection by a line which bisects; and from the point of bisection as a center, with half the length of the line as radius, describe an arc to form the upper part of the curve. There are many other methods of drawing this moulding. The Grecian trochilus is an elliptical or parabolic curve, the proportions of which are shown by the divisions of the dotted lines.

The Torus.—The Roman moulding is semi-cylindrical, and its contour is of course a semicircle. The Grecian moulding is either elliptical or parabolic; and although this and the other Greek mouldings may be drawn, as we have said, by one or other of the methods of drawing ellipses and parabolas, described in the first part of the work, and by other methods about to be illustrated, it is much better to become accustomed to sketch them by the eye, first setting off their projections, as shown in this plate, by the divisions of the dotted lines.

PERSONAL.

Mr. John Day, architect, Guelph, Ont., has recently returned from a visit to Kansas City.

F. G. Beckett, who for several years was a student of architecture in Toronto and at Cornell University, has entered upon the practice of his profession in Toronto.

Mr. Henry James, chief architect of the Militia Department at Ottawa, died at his residence in that city on the 28th of November, at the age of 55 years. Mr. James entered the Department of Public Works in 1878, and was appointed chief architect of the Militia Department in 1886. Prior to that time he practiced as a civil engineer.

CATHEDRAL OF THE HOLY TRINITY, QUEBEC.*

BY H. STAVELEY.

IN the Quebec *Gazette* of 8th Sept., 1796, appears an account of a great fire, which ten days before had devastated a large part of the upper town, and in the course of which the church and convent of the Order of Recollects were destroyed. The site upon which these buildings stood is that which is bounded towards the north by St. Anne street, towards the south by St. Lewis street, towards the west by Garden street, and on the east by the Parade Grounds, or Place D'Armes.

After the fire the government took possession of the property, and had the ruins of the former buildings levelled to the ground. Three years subsequently the Right Rev. Jacob Mountain, D. D., first Bishop of Quebec, induced King George III at his own cost to build the "Cathedral Church of the Holy Trinity," upon the site above designated. On the 11th November, 1799, a commission was appointed by Letters Patent, consisting of the Lord Bishop of Quebec, the Chief Justice of Lower Canada, the Rector of Quebec, and the Attorney General, for the purpose of building this church.

Plans and specifications were obtained, and Capt. Robe, of the Royal Artillery, was appointed superintendent of the work. For these services we learn that he received £300 in all probability sterling, or say $1,458. As the expenditure totalled about $80,000, we must conclude that the architect was moved by higher motives than those of the "Tariff" to perform the duties, which, after a lapse of nearly 100 years, one is willing to admit were well done. Possibly, however, the Captain's income was not altogether dependent upon the exercise of his architectural talent. Capt. Robe's own record tells us that he was materially assisted by Capt. Hill, of the Royal Artillery, to whom he gives credit for the "general plan". "The detailed plans of the several parts," however, he says, were drawn by himself. Further on we are told, that throughout, "I (Capt. Robe), had continually the aid of Capt. Hall's judgment and good taste." The unselfishness of Capt. Robe's statements makes one feel an admiration for him which is increased as we further hear from him in what manner he obtained the thoughts and inspiration which enabled him to produce the church, whose quiet dignity, pleasing proportions, and chaste architectural detail have combined to endear it to all whose happiness it is to worship within its walls; to such, it is, as many have expressed it, "a dear old church."

Following Captain Robe's description we learn that the dimensions of the church were taken from those of the Church of St. Martin's-in-the-Fields, London, and which is illustrated in Gibb's Book of Architecture, published in the year 1728. The east and west ends are ornamented with pilasters of the Ionic according to Palladio, and supporting a modillion cornice and pediment, but without a frieze. This idea was taken from the Pantheon at Rome, so executed, and was done to give more boldness to the pilasters for the intended height of the building. The pilasters project less than Palladio's rule directs, owing to the Point aux Trembles stone which, in the then state of the quarries, could not be got in masses large enough, without an "enormous expense." The pediments are surmounted with oblate vases, which at the angles of the building serve as flues for the stoves within the church. As the vases are not now on either pediments or at the angles of the building, it must be supposed that for some good reason they have been removed; as regards those which served as flues, they have been replaced with very everyday square chimney tops.

The tower, 24 feet square, contains 8 bells, which were placed therein in 1830 at a cost of $2,800—defrayed by subscription.

The whole designs within the church are of the ancient Ionic order, but from the proportions of different approved masters, according to their situation. The Venetian window at the east end is the Ionic of Vitruvius, according to Vignola. The pulpit (long since replaced by the one now in use) is the Ionic of Alberti, and is described as follows: "The ancient oaken pulpit placed in the centre, was in form a twelve-sided polygon, and was reached on either side by staircases entered from the front, and meeting in a platform in rear. Directly in front of and attached to the pulpit, was the reading desk with a door on each side, and in front of this the clerk's desk"—verily a three-decker of "ye olden tymes." As evidencing how time changes all things earthly, it may be noted that the pulpit now in use will most likely soon give place to a more elegant one, in memory of the late revered Bishop Williams, or if the memorial should take another form, than that of a new pulpit, the position of the latter must perforce be changed in view of the recent decision to place choir seats in the chancel, in consequence of which the pulpit will now be placed towards the north side of the nave.

Capt. Robe also informs us that the organ (long since departed) is a design of his own, and that the fret work of the great arch, over the nave, 41 feet from the floor, is his own, being an imitation of ancient stucco work, but deeming plaster to be an unsuitable material for this climate, had adopted wood—taking his idea from the common mode of ceiling rooms in Quebec, with board and batten, but aiming at a better effect, had crossed the battens diagonally.

The columns and entablature between nave and aisles, and supporting the arched roof, are of Ionic from Palladio, as correctly followed as wood work would admit.

The floors and pews, the bishop's throne, the gallery fronts, the chancel rails, etc., are all of oak. The columns are of pitch pine encased with "other wood," many times painted. The arched ceiling is entirely of pine, also painted. The chancel is semi-circular inside, on a radius of 18 feet. On the wall within the chancel to the south side of the altar are the "Ten Commandments," in two large tablets, having broad gilt cable borders. On the north side are two similar tablets, containing the Apostles' Creed and the Lord's Prayer.

The Bishop's throne is situated on the south side of the chancel, with the font immediately opposite thereto. Stalls are provided for the Dean, Archdeacon and Canons of the Cathedral to the number of eight seats, and as before intimated, in a few days choir seats for 24 persons will be placed in front of the clergy stalls, half on the north side and half on the south side of the chancel.

In the centre aisle there are about fifteen massive oaken benches used by the children of the Orphan Homes; they are movable, and in case of funerals and processions, are taken away, and the central aisle or passage is left clear for its full width of ten feet.

The records shew that the masons began laying the foundations on the 11th August, 1800. Service was performed in the church on the 4th August, 1804. Considering the size of the building—135 feet long, 73 feet wide and 40 feet high to eaves of roof—and its generally plain character, it may be gathered that no extraordinary speed was attained in its erection, but as substantiality and a due and proper regard for procuring dry, well seasoned wood, were in those days esteemed of more value than now, we may suppose that the length of time occupied in building the church was more a matter of choice than of necessity.

Beneath the chancel floor repose the mortal remains of Charles, Duke of Richmond, Lenox and Autugny, who died at Richmond, in Upper Canada, on the 29th of August, 1819, marked by a brass plate sunk in the floor, and the Right Reverend Jacob Mountain, D.D., first Bishop of Quebec, who died in the year 1825.

Throughout this venerable edifice are many handsome mural tablets in memory of distinguished persons, including those above mentioned; also Bishop Stuart, Lieut.-General Hunter, Lieut.-Governor of Upper Canada, 1805; Hon. John Stewart, Hon. Carleton Thomas Moncton, son of Viscount Galway; Rev. G. V. Housman, for twenty-nine years rector of Quebec, and about twenty others, all most interesting to examine, bringing to mind as they do, men and events of the century now drawing to its close, and of men who figured prominently in the ancient city in days of yore.

Stained glass windows of more or less merit also keep fresh in memory many citizens whose good deeds are worthy of commemoration. Foremost among these is the beautiful east end window, the central light containing the "Ascension," with the "Baptism" and "Transfiguration" in the side lights, symbolic representation of the four Evangelists occupying the space above and beneath the latter. This is to the memory of the second Bishop Mountain, third Bishop of Quebec. A very handsome window has also been erected to the memory of Judge Stuart and Judge Black (half brothers)—and others in remembrance of Archibald Campbell, Agnes Campbell, Geo. B. Symes, and Mrs. Young.

Strangers visiting the church are often puzzled as to the meaning of two old flags which hang in the chancel, all tattered and torn. They were formerly the regimental colors of H.M. 69th regiment of foot, and were deposited for safe keeping in the cathedral 22nd June, 1870, when new colors were presented to the regiment by H.R.H. Prince Arthur, then Lieutenant in the P.C.O. Rifle Brigade.

The splendid communion service of this church, consisting of twelve massive pieces of solid silver, was the special gift of King George III. They are exquisitely engraved and embossed with the Royal Arms and the Arms of the Diocese. The alms dish is a particularly beautiful work of art, the bottom being a representation in relief of the Lord's Supper.

Such is a brief and imperfect sketch of a venerable building dear to the hearts of many, not only of those still residing in the city of Quebec, but to hundreds whose lot is now cast in far distant parts. There are those whose early recollections of the old church come back to them in far-off India, in New Zealand, in old England, and our own North-West; and sure we are that often times their mental vision recalls the graceful proportions, the lofty vault, the antiquated oaken pews and open benches, dark with age, the curtained pew for vice-regal use, the Episcopal throne, whence has issued in their childhood's days the peaceful words of the benediction from the saintly lips of a Mountain or a Williams—the mural tablets and brasses, the stained glass windows—all make up a picture never to be effaced from the memory of those whose privilege it has been to worship within its ancient walls, and to join in the glorious liturgy of the Church of England, which has ever been rendered in this church with due dignity and solemnity.

* The writer of this article has drawn his information from a "Monograph" by J. C. Wurtele, Esq., entitled "The English Cathedral of Quebec" and read before the Literary and Historical Society of Quebec, 10th March, 1891.

TORONTO ART STUDENTS' LEAGUE

THE annual exhibition of the Toronto Art Students' League, occurring almost simultaneously with the appearance of their highly decorative calendar for 1894, brings prominently before the literary and artistic public, the existence of an institution which has been quietly working its way upward, and which, in very many respects holds a unique place among the art organizations of our country. Its history is neither very long nor very eventful. It is a story of steady unobtrusive development by a healthy natural growth from a small beginning to a sturdier and maturer vigor.

On September, 22nd, 1886, a circular was sent forth by Mr. A. H. Howard to the artists and art students of the city, calling them to a meeting for the formation of a club, which, relying on the added strength that comes from union, should be in a position to afford better opportunity for the prosecution of art studies than could be secured by any individual action. The date fixed for the meeting was Friday evening, Sept. 24th, and the place a little room at 56 King street east, kindly loaned by Mr. O. R. Hughes, and at that time and place the art faithful gathered together. It was by no means a large, and perhaps not a particularly awe-inspiring assemblage. The room was an upper room, and according to the story of some who were there, it was very decidedly "upper," with an approach to it that is said to have been much darker and much more difficult and dangerous than the passage to Hades as pictured by reliable writers of ancient times.

SUMMER SKETCHING CLASS. CHATEAU RICHER, QUEBEC.

These untoward circumstances, however, proved to be no bar to the fulfilment of the purpose for which the meeting was called. There were present Messrs. A. H. Howard, W. D. Blatchly, C. M. Manly, O. R. Hughes, J. D. Kelly, and others proposed for membership were Messrs. Wm. Thomson, Parker Newton and O. P. Staples. The usual resolutions were drawn up and carried unanimously, of course, and the life of the League dates from that meeting.

According to Mr. Howard's first notice, sketching from life was to be a special feature of the club's work, and, in addition to this, a paper had been prepared by Mr. Manly outlining a scheme for the carrying on of a series of monthly sketches on given subjects suited to the requirements of landscape and figure men. The meeting adopted these two features as the foundation upon which the club should build. Provision was made for supplying a model's "throne" and a model's own reflector lamp; several other lamps were added to the one already in their possession, and in a new brilliance as befitted a lover of light rather than darkness, the infant League set out on the straight and narrow path of art.

Someone had to send out notices and write minutes, and Mr. Hughes was made secretary; some one had to hold the money, and Mr. Howard was made treasurer; a president would only be in the way, and none was appointed.

For a time there were many ups and downs, with apparently a majority in favor of the "downs." Models continually failed to keep appointments and when they did appear insisted on being paid, coal-men clamored, the landlord had to be satisfied, and the frequently recurring minute "Resolved that members be urgently requested to pay all arrears of fees" seems to suggest an impending financial embarrassment. The rough places, however, gradually became smooth and the general state of affairs soon assumed a more hopeful aspect.

On April 1st, 1889, the institution removed to its present rooms in the Imperial Bank building, Leader Lane, and with its removal it cast off the most unsatisfactory features of the Bohemianism that had held a dominant place in its old habitation. With an increase in membership, accompanied by a corresponding increase in the financial receipts, it was in a position to make its new abode comfortable with a plentiful supply of light and heat, to procure additional furnishings and provide for drawing from the life several evenings a week instead of one as before. An elaborate constitution was framed and Mr. Blatchly was elected the first president. Mr. Blatchly successfully fulfilled the duties of this position until 1890, when he withdrew and was succeeded by Mr. Wm. Thomson, who in turn withdrew in 1891 and was succeeded by Mr. R. Holmes. The management of the business is vested in an executive committee of eleven members elected annually on the first Tuesday in March.

The committee for the present year is composed of: Mr. R. Holmes, President; Mr. J. D. Kelly, Vice-president; Miss J. M. F. Adams, Treasurer; Mr. W. W. Alexander, Cor. Secretary; Mr. F. H. Brigden, Rec. Secretary; Miss G. E. Spurr, Chairman House Committee; Mr. W. D. Blatchly, Chairman School Committee; Mr. J. Willson, Chairman Library Committee.

The League is a co-operative concern. All members share alike in meeting the expenses and enjoying the privileges. There are no paid officers or instructors. The membership fees are, for men, $3.00 for entrance and $2.00 per month during the eight working months of the year; and $2.00 entrance and $1.50 per month for ladies; and the amount received goes to pay current expenses. The treasurer is instructed to make a reserve sufficient to meet expenses of the summer months, and if any surplus remains, the library or the house-furnishings or the models' wardrobe derives the benefit of it. The institution is first and foremost a life-class, and seems to have set itself firmly in the one resolve, unalterable as the laws of the Medes and Persians, that it shall draw directly from the life, and if necessary every other consideration must bend in obedience to the carrying out of this line of action.

The life-class meets always three evenings a week and frequently as often as five evenings a week, and a programme is laid out, providing for about an equal number of nude and costume studies. For some time considerable difficulty was experienced in securing suitable models, and many are the funny stories told of models who prided themselves on their physique because it tipped the scale at two hundred pounds. This difficulty has, however, been largely overcome by a system of persistently paying the best prices and demanding the best service, and during last year out of nearly one hundred evenings there were only three occasions when models failed to keep their appointments, and their places had to be taken by volunteers from the members.

SUMMER SKETCHING CLASS—QUEBEC.

The lighting of the place was another problem that required time and patience and some ingenuity for its solution, and it was only after a long series of experiments that a satisfactory light for the model was secured. The model's light at present in use consists of several strong gas jets brought so closely together as to form practically one light, which is provided with a large reflector, while several movable joints in the pipe admit of its being placed in any position required. Then around the room, above and to the back of the members at work is a double semi-circle of gas jets provided with shades, which are designed to prevent an interference of these lights with the light on the model.

The series of monthly compositions still remains a most important feature of the League's programme of work. The life-class is intended to supply the means of obtaining an intimate acquaintance with the form, proportions and construction of the figure, together with a knowledge of the textures of drapery and the folds it assumes under varying conditions; and an acuteness of perception, an accuracy of drawing and a facility in the

use of materials comes from the constant exercise in these directions afforded by the work of this class. All these are, however, only the language with which the artist speaks, the medium through which he has to set forth his thoughts, and the composition class is designed to afford him a familiarity in the application of his language to the expression of his ideas in an artistic way. Three subjects are announced every month and the compositions brought in on the first Monday of the following month. "The Wayside Inn," "The Path through the Orchard," and "In Durance Vile" are the subjects for the present month, and give

LIFE CLASS—A NUDE STUDY.

a very fair idea of the character of the subjects selected. Taking one of these as a title, each member is supposed to prepare an illustration in black-and-white or color, choosing his incident, arranging his leading lines and distributing his masses of light and shade according to his own conception of the subject and his own ideas of what a pictorial composition should be.

The drawing from photographs is of a somewhat similar character. There are many of the League members who "press the button and do the rest" with no mean power, and their work does good service in this department. A suitable subject containing some point of pictorial value is selected and a number of prints of it distributed among the members. Each one, then, taking the prominent point in the print for the basis of a composition, adds figures or other accessories as his imagination suggests or the requirements of the subject demand. The illustration we present by Mr. D. F. Thomson, is from a 4×5 snap shot showing only the cow with a glimpse of the river bordered by trees. When the sketches are brought in they are numbered, and tickets marked with corresponding numbers are drawn by the contributors from the official League hat, and sketch No. 1 becomes the property of the holder of ticket No. 1, and so on until the collection is disposed of.

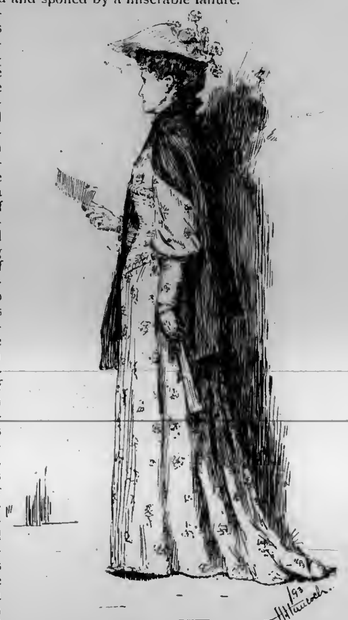
The N. D. S. L. club is a feature of the League's work which makes very serious demands upon the patience and perseverance of its members. A story is told of a musician who affirmed that a day's neglect of practice could be felt by himself, that two days' neglect was noticeable by his friends, while on the third day the public was sensible of the falling off. The N. D. S. L. club has been formed in the League to encourage among its members a system of every day practice in their work. The title is formed of the initial letters of the motto "Nulla Dies Sine Linea" (no day without a line), and every member of the League who is prepared to undertake the making every day of a sketch, however pretentious or however slight, is recognized as a member of this inner circle.

In addition to the life-class and business evenings an evening is frequently given over to the reading and discussion of papers on art matters prepared or selected by the members, followed on special occasions by "a trifling foolish banquet" with the singing of many songs and the telling of many tales. A favorite recreation for a part of such an evening is five-points. For this idle diversion, pieces of paper of uniform size are prepared and marked with five points jotted down pretty much at random, and a serious struggle ensues as each one wrestles with the problem of constructing a figure with hands fitting on two of the given points, feet on another two and a head on the fifth.

The months of summer are spent in the woods and the fields. Every Saturday is set apart for sketching excursions by the whole League, and smaller meets are generally held on Wednesdays, while special arrangements are made for more extended trips covering several days or several weeks, and in this way during the summer as well as the winter, the members are held together by a bond of common interest; and the loyalty to their institution so eminently characteristic of the League membership is not to be wondered at when one considers how intimately the interests of the individual are bound up in the interests of the body.

At the close of the summer an exhibition of the summer's work is held. It is a private exhibition to be viewed only by the members themselves and their intimate friends. There is no jury; the committee hang successes and failures alike, and many are the lessons such a collection can teach, with here a scrap of scribbler-paper bearing a delightful sketch and there a piece of good paper dirtied and spoiled by a miserable failure.

The public exhibition is always held in December. An interesting feature of the last two of these has been a collection of the original drawings contributed to certain publications prepared by the League, with a collection also of negatives, printing blocks and proofs illustrating the processes of reproduction employed. Made up as it is of persons engaged in practical art work the League had for some time entertained the idea of issuing some such illustrated publication, and this idea took practical shape in 1892. Arrangements were made for publishing a calendar for the following year, and early in December it put in its appearance in the form of a booklet of 24 pages with a lithographed cover in pale blue and gold bearing the title "Ninety-Three." There were 12 pages of drawings made up of four calendars of three months, each and illustrations characteristic of the Canadian seasons contributed by different members of the League, while on the opposite pages were appropriate quotations from the verses of Canadian writers. The favor with which this attempt was received encouraged the League to further efforts in the same line, and the kindly accorded co-operation of a number of literary people has made possible the production of "Ninety-Four," with a genuinely high degree of literary and artistic excellence. The literary part of the book consists of hitherto unpublished



LIFE CLASS—A COSTUME STUDY.

verses by a number of the poets of our country, and as many as fifteen members of the League are represented by drawings, which consist of decorative settings harmonizing with the character of the literary contributions, four calendar pages and four full-page drawings illustrating the seasons. The cover is from a delicate and graceful design in purple gray, carmine, gold and white by Mr. A. H. Howard, and the excellence of the printing and engraving is assuredly a matter of very gratifying surprise. In these publications all the contributions have been volunteered purely as a labor of love, and no member personally derives any pecuniary profit from their success. If the venture prove profitable financially the surplus goes into the general locker, and as the League relies entirely on its own resources without support from the government or wealthy patrons, its treasury frequently has plenty of room for additions.

PROPOSED CANADIAN INSTITUTE OF ARCHITECTS.

At a recent meeting of the Montreal members of the Province of Quebec Association of Architects, Mr. J. R. Gardiner gave an address on the desirability of forming a Canadian Institute of Architects, and suggested the following as a basis of organization :—

Membership to consist of all members of the four provincial bodies, viz, Ontario, Quebec, Maritime Provinces and the Western Provinces. Any architect in the Maritime or Western Provinces to be made a member direct to the Canadian Institute instead of through the Provincial body until having a body of their own.

The Council of the Canadian Institute to consist of members of the four provinces elected by their several bodies. Each Province to select two members for the first 50 members on their roll book, three members if more than 50, and four if over one hundred. The province of Québec to be represented by not more than two out of three or four members out of one nationality. In case where there is no provincial body, members of that province will be able to vote through the Dominion body.

The duties of the Dominion Association will be : 1, To amend the charter, which is to include a tariff of professional charges, which is to be passed in the Dominion Parliament so as to be legally the same throughout the Dominion, a copy of the tariff to be sent to every member; 2, To set examination papers which are to be sent to the provincial bodies on the same date, and where there are sufficient numbers of candidates to be worth while having an examination. The said examination papers to be returned after the examination, sealed, to the Canadian Institute, who will examine same and report at their meeting; 3, To set rules for the guidance of members in competitions; 4, To hold competitions for members and students at which prizes and travelling studentship will be awarded annually; 5th, To decide any arguments brought up by the provincial body; 6th, The Council to meet semi-annually in Toronto and Montreal. The first meeting to be in Toronto.

POINTS ON HEATING.

ONE of the greatest, if not the greatest, natural force in existence for the carrying off of heat is wind, and when we know something of the effects of wind in cooling buildings we learn to consider it more carefully, and plan more thoughtfully for the admission of light. For instance, in experiments with glass houses, a room heated to 70° with the outside temperature at zero, in still weather the inside temperature will be lowered 20° in five minutes and 45 seconds; with the wind blowing three miles an hour the same result will be attained in two minutes and thirty-five seconds. When, however, this wind reaches a velocity of 27 miles an hour the time required to lower the temperature 20° is only 48 seconds. Now it will be readily seen of what vast importance is the consideration of this one element alone, especially when we remember that there is hardly a day passes during the cold weather in our climate, where the velocity of the wind does not reach and many times go beyond the latter figure.

The materials entering into the construction of a building all have a known conducting power, and had we time and space we could give the ascertained conducting power in tabular form. It is not the intent of this short article to go into details, but in a few instances to give the reader some points of vital importance provided he intends to build.

The manner in which a building is put together determines largely how much of a plant will be required to heat it comfortably. If built in a loose manner, so that, as the saying is, "you can through a cat through the crevices," no heating engineer, however expert a calculator he may be, could tell to a certainty, how much heat would be required; for ofttimes a building of this construction will require many times more heat than one well built.

People often remark that were they able they would build a brick house, believing that such a house would be much warmer than a frame one. But on the contrary, experiment has shown that a frame building lathed and plastered inside, and covered outside with paper felt, sheathed and clapboarded, will lose seventy-five per cent. less heat than a brick one of the same thickness of wall. There is a loss of about 25 per cent. more heat without the paper felt than with. There is another thing that people do not often think of in the construction of buildings and that is the amount of glass that is used in the building of the structure. More window surface than just enough to properly light a room is a constant expense in cold weather and the expense is no inconsiderable amount when the time extends over a period of years. The comparative loss of heat between a square foot of glass and a square foot of 12 inch brick wall is as 1 to 6, that is a square foot of glass will lose as much heat as 6 square feet of 12 inch brick wall. Not many people consider the advantages to be obtained by the use of what is termed the double sash. Careful experiments show that when fitted with this kind of sash 75 per cent. less heat is lost than with the single window.

TORONTO ART STUDENTS' LEAGUE—DRAWING FROM PHOTOGRAPH.

NOTES FROM ST. JOHNS, N. F.

AS everyone knows, the city of St. John's has untortunately suffered from two large conflagrations; that of 1846, however, was not so disastrous as the recent one, which broke out after six weeks drought when everything was dry as tinder; owing to this and the high winds then raging, it soon got beyond control, and before night the whole of the eastern and central portions of the city was in flames. It must have been a magnificent sight, harmonizing well with the rugged grandeur of its surroundings, and enough even to satisfy the ultra-æsthetic cravings of a hero.

The loss was very great; all the principal public buildings were destroyed, as also were the leading wholesale and retail houses and the better class of residences. Except on the main thoroughfare, Water street, where it has been a necessity since the fire of 1846 to build in some incombustible material, there were very few brick or stone buildings. This fact explains to a certain extent the fire getting so great a hold on the city.

From an architectural point of view the most unfortunate occurrence was the burning of the Church of England Cathedral. This, said to be the finest specimen of Gothic on this side the Atlantic, was one of the masterpieces of the late Sir Gilbert Scott. It was designed in the style of the Early English period of Gothic, and even in its ruined condition, one can see how successfully the designer mastered his problem. The effect is obtained more by perfect proportions and careful massing of the parts than any elaborateness in detail—resulting in a noble piece of architecture.

The nave was started as far back as 18?—, but the chancel and transepts were only completed a few years before the fire. Even then the building was not finished, as it still lacked the upper portion of the large central tower. Some are sanguine that it will yet be finished, but it is to be feared that many years must pass before this consummation. Only the outside walls of the nave are left standing, the whole of the stone arcading being a mass of ruins. The chancel and transepts, although badly damaged, did not suffer so much as the nave, and these portions of the cathedral are being restored to be used by the congregation till funds permit of the whole building being finished.

It is both surprising and refreshing to find such an architectural monument in this country of fog and ice, which one usually thinks of only in connection with cod fish and seals, and which during part of the year is surrounded by a small army of icebergs, looking like so many ghosts as they silently glide by. The unexpectedness of such a thing no doubt lends an additional charm, and the building, set off by a background of rugged picturesqueness, is a pleasing sight to the stranger.

For some time after the fire the burnt-out portions of the city presented a novel and curious spectacle—streets and streets of ruined houses, and in the majority of cases only heaps of rubbish to indicate what had once been. Here and there where had stood a number of frame buildings, one would come across a perfect forest of chimneys, standing stark and bare, some looking like grim pillars set up to commemorate the fiery scourge, and others, where two breasts had been brought into one stack, like great Gothic arches of a ruined cathedral.

Some very quaint bits were to be found; indeed it needed very little sometimes when looking at a building with the electric light streaming through window openings and fissures, to imagine onesself back in the Old Country viewing some old castle or abbey by moonlight. The stunted and blackened piles of the wharves show to what an extent the fire went; not only this, but the sidewalks were completely destroyed, as were also the fish flakes on the eastern side of the harbor where the cod fish used to be dried.

The burning of the cathedral was not only the unfortunate happening of the fire, but it was the most unexpected, for everyone considered it fireproof; this belief was really the cause of its destruction, as the interior was filled with furniture and goods by those whose homes were burning, and although the cathedral stands in an isolated position, the heat of the fire ultimately cracked the lead glazing, the sparks flying through the chaotic mass of household belongings stored therein, and before anything could be done the entire building was filled with furious flames, bursting out through the roof and licking the stone walls as if greedy that nothing should be left. This instance gives some idea of the fierceness of the fire and its unrelenting hold.

The city is built around the harbor—one of the finest in the world—and rises picturesquely from the water's edge. When entering the "Narrows" one sees row upon row of houses, each one seeming to spring from that below. The view culminates in the two cathedrals, which stand like sentinels over the city, forming a fitting apex to the grouped up medley of walls and roofs. The extreme hilliness of the place renders building in some parts somewhat more difficult than usual, nor is this the only obstacle, for the city is built on solid rock, which necessitates a great deal of blasting. On the harbor side of Water street, however, there is much made up ground, and here piling must be resorted to before anything can be done. In one respect Water street when rebuilt will be much improved. Before the fire all or nearly all the buildings were finished with pitched roofs in such a way that the unfortunate pedestrian in winter often had to run for his life. This can still be witnessed in the old portion of the city. In the new buildings the roofs are all flat, as they should be when brought out to the street line in a climate like this.

Of all the new buildings put up on Water street at present, not more than a dozen can lay claim to any architectural merit, for the jerry builder has been at work, and some awful looking piles of brick and mortar meet the eye. Where he has attempted anything it is only a futile effort to copy some architect's design, with the usual result of poor detail, absurd proportions, and general incongruity.

There will be one part of St. Johns with a group of buildings worthy of any city, for within a stone's throw of the two cathedrals will be the Church of England Synod halls and schools with residences, the Presbyterian church, the Methodist college, the Gower Street Methodist church, the Congregational church, Presentation Convent, the Christian Brothers' College, the two Bishops' residences, and the Anglican clergy house. The locality, which might appropriately be called "The Architectural Square," is well-chosen, for the gently rising ground gives a pleasing relief and masses the buildings well one with another. The government and other public buildings in different parts of the city will certainly add to its architectural attractions, but beyond these and the buildings already mentioned there will not be anything that should be called architecture. There are a great many frame buildings springing up like mushrooms all over the place, having no particular merit but that of fulfilling their primary purpose of affording shelter from the elements.

St. John's has been a busy place during the past summer, and much has been done to obliterate traces of the fire. Even now, though, these are only too apparent. There will be less building next season if one can judge from present indications, and after that, affairs will be pretty much in their normal condition.

C. H. A. B.

THE CENTRAL ONTARIO SCHOOL OF ART AND INDUSTRIAL DESIGN.

Architects should take an interest in the progress of this school and it would be well for architectural students to attend some of its classes. The school is now in its fourth session and is steadily growing. The course is based upon study from the antique and from life as the means of highest training for eye and hand in preparation for design of all kinds. These classes, which are under the care of the best instructor procurable in Toronto, form the whole course for some students who are aiming merely at skill in drawing and painting. But the ultimate aim of the school is to form a centre of education in the arts of industrial design as well as in the graphic arts. On the board of directors are, besides artists and architects, several of the leading manufactures and producers of objects requiring design. Work in the precious metals, lithography and engraving, furniture, carpet weaving, stained glass and decoration are all represented on the board. An analysis of the students' register shows among the students lithographers, glass stainers, decorators, designers, carvers in wood and stone, cabinet makers, jewellers, painters and engravers. Efforts are continually being made to extend the usefulness of the school in the direction of teaching industrial design. The larger the school becomes the greater will be its power of enlarging this department. For this reason it is to be hoped that it will continue to increase and be such a centre of teaching in art as will realize its name to the full. It is better to have one good school than many indifferent ones. Centralization of schools means concentration of the students' fees and power therefore to employ the best teachers. One teacher can handle many students, and there is a distinct gain to the art student in being one of a large number rather than one of a few. In no other class of work is the benefit of association with others so great. The students in the large ateliers of Paris derive as much benefit from their manner of working together as they do from the occasional visits of the great man under whose name they are associated. It would be a good thing for Toronto and for the country if this school can fostered so as to become a great central school of art with funds large enough to attract to its teaching staff men of the best class.

It is worth pointing out to architects that subscribers of $10 per annum are entitled to send one student to the evening classes. It may sometimes be worth while to invest this much in training a promising student who cannot himself afford to pay for instruction.

PAINTING INTERIOR WOODWORK.

Some people seem to think that as soon as wood is used inside a house, there arises a deadly sin against the proprieties if it be painted, and hence all interior woodwork should be finished in its natural colour and grain. How can they reconcile the uncompromising hardness and coldness with which an unstained or unpainted piece of oak or white pine will obtrude itself into any scheme of decoration consisting of soft warm colours. It were far better to stain the wood in harmony with the general decorative effect—not to imitate some other wood, be it understood, but to get the desirable colour, for harmony with its surroundings. But really there can be no objection to good honest paint in soft, flat colour, or in brilliant and polished china gloss if it be desired. If it be honest to paint the outside of our dwellings in colours to please us, what harm can there be in choosing such colors as may be agreeable for our inside finish, and boldly painting the woodwork to suit our decorative scheme? This idea is gaining ground, and the area of varnish-finish is almost ended; or at least the time when varnish alone was considered to convey a title to respectability, and when painted interior woodwork was supposed to be sure indication of poverty and social inferiority, for now even the richest and most favoured socially dare to paint their woodwork, if its suits them best to do so.—*Furniture and Decoration.*

CANADIAN BUILDING STONES AT THE WORLD'S FAIR.

A PROMINENT and interesting feature of the admirable collection of Canadian minerals shown at the World's Fair, was the variety of specimens of building stones from the several provinces of the Dominion. These specimens were collected by the Dominion Government Survey at Ottawa, and by the Ontario Government Mining Bureau, Toronto, and from these sources we have obtained the particulars hereinafter printed in regard to them:

In material of this description, Ontario is particularly rich. Many excellent varieties of limestone, freestone and sandstone occur. The first named yields an excellent quality of quicklime. The Guelph dolomites are well adapted for building purposes. The hard, close grained, Kingston limestone is quarried from beds varying in thickness from six inches to a foot, and although of a dark grey color when fresh, it bleaches to an agreeable whitish hue in the course of a few years.

At many places the crystalline limestone is fine enough to work as marble. At Dorion in Thunder Bay District, it is of a flesh color, variegated with veins. Elsewhere in the stone district is found an argillaceous limestone of a milk white, branded with pale grey, and of a rich brown and pale green (mottled), known as Penessie Marble. Another variety called "Serpentine Marble," possesses good colors, but does not take a high polish. Renfrew County yields the largest quantity of marble for commercial purposes.

Good marble, black, white and pink is found at Madoc in the County of Hastings, and Barrie township in Frontenac County.

At Cornwall, on the River St. Lawrence, a fairly good quality of black "marble" is being worked.

Extensive deposits of Medina sandstone are worked at the Forks of the River Credit in the County of Peel.

Several points along the north shore of Lake Superior yield sandstone of the very best quality.

Good granite, rich in color and free from flaws, is found in many places; West of Fort William it occurs of a brownish grey in some localities, elsewhere it inclines to a pale purple. Near the City of Kingston the color strongly resembles that of Peterhead granite, but is a brighter red.

Black Syenites are found along the north shore of Lake Superior.

In addition to Ontario's exhibit, there were shown at Chicago some fine samples of sandstone of a fine grained nature by New Brunswick, Nova Scotia, North West Territories and British Columbia, together with a large collection of marbles and granites from various parts of the Dominion shown by the Geological Survey.

The following particulars of the character and variety of Canadian exhibits of building stones, the purposes for which they seem to be adapted, and the sources of supply, are expected to prove of much interest to architects, engineers, builders and others interested in knowing what native material in this line is obtainable.

LIMESTONES.

John Hyslop, Goderich, Ont.—Six-inch cube of limestone, dressed—About thirty feet of this rock, in beds from three to six feet thick, is exposed in a cliff at Mr. Hyslop's quarry, and large blocks can be easily obtained. The stone makes good lime, but is chiefly used for building purposes. The piers of the Maitland bridge at Goderich, and the Goderich Jail are built of it.

Geological Survey—Six-inch cube limestone, dressed—From the quarry of Mr. White, Pembroke, Ont. The beds are from three to twelve inches thick. The stone is largely employed in the town of Pembroke, and has been used to some extent for bridges, &c. An analysis of a specimen, similar to that exhibited, gave,—carbonate of lime, 83·96; carbonate of magnesia 9·29; carbonate of iron, 0·69; insoluble, 6·06.

Geological Survey.—Six-inch cube of limestone, dressed—From the quarry of Mr. John Mahoney, Que.

Geological Survey.—Six-inch cube of limestone, dressed—From the quarry of Mr. C. B. Wright. These quarries have been extensively worked for a long time, the beds, which are almost horizontal, having been removed over a large area for a depth of fifteen feet. Blocks ten by five by three feet can be taken out, and are sold at from 25 to 35 cents per cubic foot. Most of this stone is used for building purposes in the city of Ottawa. The upper portion of some of the beds presents a banded structure, the lower portion being finely granular. The stone is easily dressed and susceptible of high polish and sharp tooling.

Geological Survey.—Six-inch cubes of grey and white limestone, dressed—From an extensive band of crystalline limestone at Portage du Fort, Lichfield, Que. The beds, which vary in thickness, are sometimes grey in color, alternating with others which are almost pure white. The stone takes a good polish and weathers evenly.

Duddswell Marble and Lime Co., Marbleton, Que.—Six-inch cube of limestone, dressed.

Geological Survey,—A six-inch cube of limestone dressed—Montreal, Q.

Geological Survey.—A six-inch cube of limestone, dressed—Point aux Trembles, Q.

Worthington & Co., Montreal, Q.—Six-inch cube of limestone, dressed—At the quarry of Messrs. Worthington & Co., Terrebonne, Q., the beds of limestone worked are from eight inches to four or five feet thick, and are cut by joints from ten to forty feet apart, which greatly facilitates the quarrying. The stone is of excellent quality, and blocks of any required size can easily be obtained. It is carried to Montreal, a distance of sixteen miles, in scows towed by steam tugs.

Charles Dussault, La Chevrotiere, Q.—Six-inch cube of limestone, dressed—The Trenton formation, which is the next in succession above the Birdseye and Black River, yields excellent building stone, at Montreal, at Chevrotiere nearly forty miles above Quebec, and at many intermediate places. The beds are from three to eighteen inches thick at the bottom, passing toward the top into a black nodular bituminous limestone; which is interstratified, in irregular layers of from one to three inches thick, with black bituminous shale.

Public Works Department, Quebec, Q.—Six-inch cube of limestone, dressed, from Deschambault quarry, Que.—In this quarry the beds vary from nine inches to three feet in thickness, and the finest stone suitable for all the better class cut stone work can be obtained. It has been used extensively in the cities of Quebec and Montreal for the last thirty years.

Geological Survey.—Six-inch cube of dolomite, dressed—This greyish-brown dolomite is from the quarries of the Canadian Pacific Railway, and Mr. McEwan, at Beckwith, Ont. It is used for window and door sills, and also largely for general building purposes. The stone when first quarried is very soft, but hardens on exposure. The roundhouse at Brockville, as well as bridges and culverts along the line of the Brockville and Ottawa Railway, are built of it. Blocks 3 × 3 × 15 feet can be obtained.

The following exhibits were included in the Ontario Government collection:

P. A. Johnston, St. Davids, Ont.,—Six-inch cube, dressed, from Queenston Quarry.

Union Co-operative Stone Co., Thorold, Ont.—Six-inch cube, dressed from Thorold quarry.

Robt. McInnes, Owen Sound, Ont.—Six-inch cube, dressed.

T. J. Kilpatrick, Kingston, Ont.—Six-inch cube, dressed, from Wolfe Island Quarry.

John Battle, Thorold, Ont.—Small rough block,

D. Kennedy, Guelph, Ont.—12 inch dolomite cube, dressed; 6 × 9 block, dressed.

P. A. Johnston, Queenston.—Paving block.

Geo. Farquhar, Toronto Stone Co., Toronto, Ont.—twelve inch cube, dressed.

Dressed Magnesian blocks, from Elora, Ont.

Robt. L. Gibson, Beamsville, Ont.—Dressed block, 2 × 1 × 1 foot.

City of Ottawa.—Dressed and polished block, 20 × 12 × 7 inches.

Town of Thorold.—Cubic foot, dressed and polished.

Town of Fergus.—Magesian block, black, dressed.

Mr. White, Anderton, Essex Co.—9 inch cube.

Pelee Island, Ont.—Six-inch dressed cube.

SANDSTONE AND FREESTONE.

The following exhibits were included in the collection of the Geological Survey, Ottawa:—

Vancouver Coal Mining and Land Company, (Limited), S. Robbins, Supt., Nanaimo B. C.—Six-inch cube of sandstone, dressed.—From quarries on Newcastle Island, B. C. Among the coal-bearing rocks on Newcastle Island there are beds of brownish-grey sandstone, which afford excellent material for building and flagging stones. The upper beds are of the best quality, and it was from one of these that Mr. E. E. Emery, of San Francisco, obtained the stone for the construction of portions of the mint in that city. Blocks for pillars were taken out, which after dressing were twenty-seven feet six inches in length, and three feet ten inches in diameter. Flagstones, with even surfaces, as much as ten feet square, have also been obtained, and are easily quarried, and it is not unlikely that some of the measures will afford good grind-stones.

The Chicago and Verte Island Stone Co. of Chicago, U. S. A.—Six-inch cube of sandstone, dressed.—From quarries on Verte Island, Nipigon Bay, Lake Superior, Ont. This stone is known to have a thickness of thirty feet. The upper bed alone is twenty feet thick. Mr. Geo. P. Merrill, of the United States Geological Survey, recently made a microscopic examination of it, and found it to be composed of quartz and felspar, with a very little mica. The crushing strength is reported to be 11,500 lbs. to the square inch. Thus far it has been used principally in the United States.

Credit Forks Stone Co., Credit Forks, Ont.—Six-inch cube of sandstone, dressed.—From quarries at Caledon, Ont. The brownish-red variety of the stone occurs in beds six feet thick, and is underlaid by a greyish or whitish sandstone. The beds have been stripped over an area of four acres and the stone removed to a depth of fifteen feet.

Six-inch cube of sandstone, dressed.—From Skead's quarry, about four miles from Ottawa. The stone is very fine grained, of a brownish grey colour, and would make handsome buildings. It appears, however, to be difficult to quarry, the blocks obtained being of very irregular form, owing to somewhat conchoidal fracture. A dressed specimen, about seven feet long, may be seen in the coping of the wall round the grounds of the Parliament Buildings at Ottawa, but it can only be distinguished from the adjoining blocks of Ohio stone by its finer texture.

Six-inch cube of sandstone, dressed.—From Mr. John Rankin's quarry, near Pembroke, Ont. The stone occurs in beds from six to twenty inches thick. It is easily worked, and although soft, is tough and retains sharp angles. The Pembroke court house is built of it, and it is sometimes employed for making monuments.

Caledonia Freestone Company.—Six-inch cube of sandstone, dressed.—From quarries at Rockland, N. B.

R. B. Heustis.—Six-inch cube of sandstone, dressed.—From quarry at Wallace, Cumberland County, N. S.—The specimen contributed by Mr. Heustis is from a quarry at Wallace situated about 150 feet above high water mark, and only 600 yards from a good harbor. The beds are horizontal, and for the first fifteen feet from the surface vary in thickness from four inches thick to two feet; below this there is a massive bed, which according to Mr. Heustis, is from three to eight feet thick. It is divided into rectangular masses by joints from six to fourteen feet apart, which greatly facilitate the quarrying. The price of the stone delivered on board vessels in the harbor is from forty to sixty cents per cubic foot. Blocks containing 160 cubic feet have been shipped. The quarry is held by a stock joint company.

Nova Scotia Advisory Board.—Nine-inch cube of brown sandstone, dressed; nine-inch cube of chocolate sandstone, dressed.—From McKenzie's quarry, Pictou, N. S. In addition to the above, the Nova Scotia Advisory Board exhibits eleven dressed specimens of sandstone and two of limestone, from various localities in Nova Scotia.

The following exhibits were included in the Ontario Government collection:—

Carroll & Vick, Toronto.—Six-inch dressed cubes brown and grey freestone; block of Credit Valley brown freestone, (medina formation) 2′ 7″ × 2′ 3″ × 2′ 10″. The top is artistically carved in Romanesque style, having in the center of carving a shield bearing the Ontario coat of arms. These specimens were taken from Credit Forks Quarries, 40 miles north west of Toronto, on C. P. R railway.

Dressed block freestone (banded) from near Perth, Ont., also twelve-inch dressed cube (double banded), twelve-inch dressed cube (white,) window sill (white), from same locality.

Chicago and Verte Island Stone Co., Port Arthur, Ont.—Dressed six-inch sandstone cube; dressed six-inch cube (red).

P. M. McDonald, Perth Ont.—Half dressed six-inch cube.

Indian Mission Quarry, McKay's mountain, Thunder Bay.—Specimen argillaceous sandstone.

C. F. Gildersleeve, Kingston.—Small rough block red sandstone, from quarry near Kingston; sandstone modules, sandstone (red and buff banded) and sandstone (deep red) from Cataraqui Quarries.

McKellar Bros., Fort William, Ont.—Small rough block white sandstone; half dressed six-inch cube from quarry at Rossport, Nipigon Bay.

J. C. Goddard, Toronto, twelve-inch dressed freestone cube, from quarry Orangeville, Ont.

GRANITE.

The following exhibits were included in the Ontario Government collection:—

Rat Portage collection (no locality given)—large rough hewn blocks, colors red and grey, and from Ignace station on the C. P. Railway, 150 miles west of Fort William, a block (banded gneissoid) 5½ × 5½ inches, dressed and polished, also block 6½ × 10½ × 8 inches, dressed and polished. The material is said to exist in immense quantities in the locality from which these specimens were taken.

From Pearl River Station, Township of McTavish, west of Black Bay, Lake Superior.—A six-inch cube dressed and polished and a block 5 × 5¾ × 8 inches, dressed and polished. This stone is wine color, of fine grain, and

seems well adapted for monumental work, pillars, etc. It exists in area of many square miles.

From Kingston, Ont.— Block (red) 6 × 10 × 6¾ inches, dressed and polished; round column (red) 7 inches high and 5 inches in diameter; seven-inch cube (red) dressed and polished; tapering pillar (red) 22 inches high and 6 inches square at base, polished.

W. C. Caldwell, M. P. P., Lanark.—Two large blocks, dressed; polished on one side. The location in Renfrew County, from which these specimens were taken is an extensive one. The quality and color of the stone are excellent. Mr. Caldwell also showed small polished specimens from various localities in the Counties of Frontenac and Lanark; small specimens, illustrative of various localities in Ontario, from Lake Huron to the Ottawa Valley, and a large block (red) dressed and polished on one side, from the north shore of Lake Huron.

The following exhibits were included in the collection of the Dominion Geological Survey:—

R. Forsyth, Montreal—Cube of granite.—From Beebe Plain, Stanstead, Q.—Granite occurs in abundance in Barnston, Stanstead, and elsewhere in the "Eastern Townships" of the Province of Quebec. In the last-named township it occupies an area of six square miles. The granite is composed of white quartz, white felspar, and black mica, and takes a fine polish. It is easily worked, and in many localities can be obtained in blocks of any required size. The new Eastern Townships Bank at Sherbrooke is built of it, and it was used many years ago for bridges on the St. Lawrence and Atlantic Railway. Mr. Forsyth also exhibited a 6 inch cube dressed, and a small column, dressed, from quarries at Birch Cove, Halifax, Nova Scotia.

Milne, Coutts & Co., St. George, N. B.—Red granite, polished.

Hon. John Young, Montreal.—Specimens of salmon-red syenite, from the east side of the harbor of Kingston. The rock is exposed for a length of more than a quarter of a mile, with a breadth of upwards of 100 yards, and has a face of ninety feet, overlooking the harbor. It dresses easily and takes a fine polish.

Bay of Fundy Red Granite Co.—A monument of red syenite polished, three feet two inches square at the base, and fifteen feet high. Value $1000; four head-stones polished; two urns; from quarries at St. George, Charlotte County, C. B.

MARBLE.

The following exhibits, formed part of the Ontario Government collection. In every case except that of Renfrew marbles, the specimens were obtained from surface deposits. At Madoc and Hungerford a little has been done by way of development, but not enough to test fully the qualities of the deposits:—

Jas. E. Harrison, Bridgewater, Ont.—White dressed and polished specimens and a grey and white banded six-inch cube, dressed; white column and base; specimens of grey marble.

J. Smith & Co., Sydenham, Ont.—Small blocks of pale green clouded and pinkish white, half dressed and polished on one side; and a grey banded block 6½ inches, polished.

C. P. Brown, Sault Ste Marie.—Small rough specimen of green clouded, from Echo Lake, Thunder Bay.

From 20 miles west of Wolfe River Station on the Canadian Pacific Railway, Thunder Bay District, a small block, black and grey, 5¾ × 5¾ × 3 inches, polished—It occurs plentifully as a horizontal bed about twenty feet thick, interstratified with indurated red marble, and with marble of other colors. This is a beautifully variegated marble that might be effectively utilized for mantels and other indoor work. From the same locality was shown a small slab 6 × 13 × 1 inch, light purple, veined with greenish grey and brown.

From west of Nipigon Station, a slab 21 × 9½ inches, polished, of so-called Nipigon marble.—Plentiful on line of Canadian Pacific Railway, close to Nipigon Bay. Approaching argillite in composition; does not take a high polish.

Collections of "Marbles" from Nipigon series, Wolfe Lake, Thunder Bay District.—This handsome collection of polished cubes, varying in size from two to six inches, represents material said to exist in considerable quantities. Though not susceptible to high polish, they are rich in color, the tints varying from a mellow grey, through deeper shades to light pinks, purples, greens, and browns. Some are banded, some clouded, and others veined. For mantles, panels, mosaics, and interior work of various kinds, they produce a good effect. In quality they are too argillaceous to be classed as true marbles.

The following exhibits from Madoc, Ont., were made by Mr. P. W. Ellis, Toronto, for the Hungerford Marble Co.—Small block, black, 6 × 6 × 3½ inches; paper weight, black, 3½ × 3 × 1 inch; paper weight, black, with white streaks, 3½ × 3 × 1 inch; turned paper weight, pink; turned paper weight, grey, dark mottled; turned pillar cap, grey, dark veined, 13 inches high; slab, white, for table top 20 × 24 inches; white, turned pillar, 14 inches high; white card receiver; pillar, black, 6 feet 6 inches high; white block, 8 × 9 × 9½ inches, dressed and polished; white, 10 inch cube dressed and polished.

Crescent Gold Mining Co., Malone, Ont.—White slab, 7 × 30 inches, reported to possess excellent working qualities.

The following specimens were obtained from the Sanford property, township of Barrie, County of Frontenac:—

Pink of rich tint, small pillar 13 inches high; pink, block 6½ × 6 × 5; pink, slab 12 × 8 inches; white slab 13¾ × 14¾ inches; white turned pillar 17 inches high and 5 inches in diameter; grey, with brown veins, pillar 14 inches high and 4 inches diameter; white slab 10¾ × 15¼ inches; grey, light clouded, slab 10¾ × 15¾ inches dressed and polished; pinkish white with dark grey veins, slab 10 × 11½ inches, dressed and polished; white, with brown veins, small pillar 14½ inches high, 4¾ inches diameter, dressed and polished; white, with brown veins, 9 × 11½ × 2 inches, dressed and polished; white, with brown veins, 6 inch cube, dressed and polished; white, 6 inch cube, dressed and polished; grey, small block 6 × 6 × 5 inches, dressed and polished; grey, small block 5 × 5 × 4 inches, dressed and polished; greyish white, with dark grey veins, dressed and polished.

The following exhibits were included in the collection of the Dominion Government Survey:—

From Mount Mark, near Horne Lake, Vancouver Island.—Short column and pedestal of marble.—The crystalline limestones of Mount Mark occur in very thick beds, interstratified with diorite. They are capable of affording a great variety of marbles suitable for ornamental purposes, though not fine enough for statuary. White, dove-gray, and bluish tints are the most common; but some varieties contain reddish and greenish bands. Large blocks, entirely free from flaws, could be easily obtained.

From Arnprior, Ont.—Marble, striped, light and grey.

From Gloucester, Ont.—Brownish grey specimens.

Grenville, Que.—Yellowish-white.

Point Claire—Brownish black and greenish black specimens.—In the township of Grenville and its augmentation, a band of crystalline limestone, containing *Eozoon Canadense*, has an extensive run through the country; and affords in many cases a peculiar variety of marble, having a white ground marked with small green spots of serpentine, which occasionally forms angular masses several inches in diameter. The serpentine usually runs in bands marking the stratification of the rock. These bands, as in the case of the Arnprior marble, are sometimes even, and at other times corrugated, giving diversities of pattern. Sometimes the serpentine, instead of green, is sulphur yellow, as in the specimen from Grenville. In many parts of the country, the Laurentian limestones are tolerably free from foreign minerals, and give white marbles. These, however, are usually too coarse-grained for statuary purposes, and sometimes they are barred with slightly different colours. Such is the case with the crystalline limestone occurring in the township of Elzevir. Many years ago, a mill for cutting and polishing marble was erected on the Calumet, but the demand for the marble was not sufficient to make the enterprise profitable.

L'Original, Ont.—Grey marble, with thickly disseminated white spots; Dark gray marble, with more thinly disseminated white spots.—The bed from which the specimen (*a*) is taken, varies in thickness from three to six inches; it is near the surface, and easily quarried, but has hitherto been but little used. The locality is a quarter of a mile from the south bank of the Ottawa, four miles west of L'Original village, and sixty-four above Montreal. The white spots are caused by small bivalve shells (*Atrypa plena*) filled with calc-spar. Of the darker variety (*b*) there are two beds, of six inches and one foot respectively near the surface, and overlying the previous bed (*a*). Blocks large enough for chimney-pieces and tables are readily obtained.

Jas. Worthington & Co.—Montreal, specimen of grey marble.

From Montreal, Que.—Specimens of grey marble from the Trenton and Chazy formations.

From St. Dominique, Que.—Specimens of dove grey and dove grey with white spots.

From St. Armand, Que.—Specimens of white, white clouded with pale green, and dove grey marked with white and black. The material, which takes a high polish, occurs in great abundance in the vicinity of Phillipsburg on Lake Champlain.—About a mile and a half south eastward from Phillipsburg there occurs a black marble, similar to this specimen. The beds dip to the eastward at an angle of about twelve degrees; a quarry was many years ago opened on one of them, which has a considerable thickness. The stone was exported to the United States, and much esteemed in New York, but the opening of quarries of black marble at Glen's Falls, where there is good water power, interfered with the demand, and caused the enterprise to be abandoned.

From Caughnawaga, Que.—Specimens of grey and grey with red spots.—Similar grey marbles with red spots (generally corals), occur in the same formation as the rock of Caughnawaga, behind the city of Montreal, and on Isle Bizard. In all of these localities the rock is filled with fossils, which are plainly seen on the polished surfaces.

From Dudswell, Que.—Specimens of cream white, striped with yellow; dark grey and yellowish, fawn yellow and white.—The specimens exhibited of cream white and yellow, and dark grey and yellow, are from beds that overlie one another. The yellow streaks in both of these marbles are composed of dolomite, while the light ground of the one, and the dark ground of the other, are of carbonate of lime. When the dark grey approaches black, which it sometimes does and the yellow streaks are narrow, the marble bears a strong resemblance to the Porter marble from Northern Italy, sometimes known as *black and gold*. On analysis, the resemblance between the two is further sustained by the fact, that in both cases the ground is a pure limestone, and the yellow veins are dolomite.

From Esquimaux Island, Mingan group.—Specimens of drab marble.—This drab coloured marble occurs in great quantity on Esquimaux Island, of the Mingan group, where the stone might be easily loaded on board of small vessels. It cuts with great facility, and takes a uniform polish.

From St. Lin, Que.—Polished slab of red marble.—At St. Lin about thirty miles from Montreal, there are massive beds of limestone, portions of which are of a red colour, and afford a good marble.

From St. Joseph, Beauce, Que.—Polished slab of red marble veined with white.—This handsome marble occurs near the River Guillaume, associated with red shales and sandstones, resembling those of Sillery, near Quebec. The bed is from ten to forty feet thick, and in a distance of half a mile on its strike is exposed in four places. The marble takes a fair polish, and could be obtained in large blocks. The locality is forty-five miles south of Quebec.

From Hull, Que.—Polished slabs, spotted green and white.

From Arnprior, Ont.—Polished slab and ten inch cube of marble striped, light and dark grey.—Near the mouth of the Madawaska, in the township of McNab, a large band of crystalline limestone is exposed. The rock contains dark bands, which are sometimes narrow and sometimes wide, producing, where there are no corrugations in the layers, a regularly barred or striped pattern. The colours are various shades of light and dark grey intermingled with white. The dark colours are due to a greater or less amount of graphite, which is intimately mixed with the limestone. The texture of the stone is somewhat coarse, but it takes a good polish. Considerable quantities were employed in the decorative work of the Houses of Parliament at Ottawa.

From Horton, Ont.—Polished slab of grey crystalline marble.—This stone has been largely employed for monuments. Blocks from a few inches to several feet thick can be easily obtained.

From Texada Island, Strait of Georgia, B. C.—Polished slab of grey marble with black spots and veins; polished slab of greyish-white marble with brownish veins.—A quarry has been worked to some extent on the shore of Malaspina Strait near the north end of the island. Marbles like those exhibited form low cliffs along the shore for several miles.

NOTES.

In the N. B. Section were shown some handsome granite monuments, exhibited by Messrs. Epps, Dodds & Co., Milne Coutts & Co., St. George; Tate Meeting & Co., St. George, also exhibited polished granites.

One large block of sandstone, dressed, was shown by C. E. Fish, Newcastle, N. B.

In the Nova Scotia section was a collection of dressed cubes of sandstone and granite exhibited by the Government of Nova Scotia.

The North West Territories supplied some dressed cubes of sandstone, exhibited by Leonard Gaetz, Red Deer River, J. G. McCallum, Calgary, A. McKay, Indian Head.

In the Quebec Court were some dressed cubes of granite, gneiss and limestone from different places in the province exceptionally fine limestone from Bryson and Dudswell was also shown, the latter constituting a very handsome marble.

The New Rockland Slate Co., Rockland, Que., exhibited a large block of slate, together with manufactured articles, such as sinks, wash-troughs, blackboards, roofing slates, etc.

When papering on white-washed walls it is necessary to first size the surface. Use good glue size and add a pint of malt vinegar to the gallon of the size. The vinegar acts upon the whiting and causes the paper to adhere strongly and permanently.

BRITISH COLUMBIA INSTITUTE OF ARCHITECTS.

THE third annual meeting of the British Columbia Institute of Architects took place in Victoria on the 2nd of December, 1893. The society comprises twenty-four members, of whom the following were elected as officers and Council for the ensuing year:

President—C. O. Wickenden, Vancouver.
1st Vice-President—R. B. Bayne, Victoria.
2nd Vice-President—C. J. Soule, Victoria.
Hon. Treasurer—E. Mallandaine, Victoria.
Council—C. E. Sharp, New Westminster; Thos. Hooper, R. E. Day, J. G. Tiarks, S. A. McClure, Victoria; A. E. McCartney, Vancouver; Thos. Honeyman, Nanaimo.
Hon. Secretary—C. E. Sharp.

The business transacted was, excepting one subject, of the usual ordinary routine kind.

The question as to whether the "Architects' Registration Bill" was to be brought before the Legislature in the coming session was discussed, and the outcome of the discussion was that it was the opinion of the meeting that it would probably best further the object to be attained, to place the society in communication with the eastern societies to ascertain what if anything was being done by them, and to consider the question as a Dominion one. With this object, the Secretary of the society will be instructed by the Council to communicate with the eastern societies on the subject.

The competition question has been unfortunately of the too frequent heart-burning and unsatisfactory character, and on a motion before the meeting it was determined to communicate with the Ontario society, obtain copies of their particulars of competitions, and if considered suitable to our wants, adopt them.

The question of the recent competition in Victoria for ward schools occupied considerable attention of the meeting. It was the opinion of the meeting that after a public competition had been called for, faith was broken with the competitors in the action of some of the members of the School Board in the selection of an inferior plan for one of the wards. A circumstance that lends additional force to this professional opinion is, that the ratepayers of the North Ward petitioned against this selection for a school building being carried out on such a design for that ward.

The report of the Council for the closing year was accepted and passed, and the meeting closed with the following address from the vice-president occupying the chair:

VICE-PRESIDENT'S ADDRESS.

In the unavoidable absence of our President, the duty of making your presidential address devolves upon me as your senior vice-president. I regret it to some extent, as the action I have lately taken in your Council may be looked upon as likely to prejudice me in my remarks when touching on the vexed question of competitions.

Since our last meeting in Vancouver, a period of unexampled dullness has prevailed in our profession—we have not a single new member to welcome; at the same time, so far, we have not a single new resignation to record, and I think with brighter times and more doing that we might count upon several new men who have not yet joined us. I hope that the seeming indifference in lack of attendance of many of our members does not foreshadow dissolution. Busier times may perhaps bring with it a little more enthusiasm and interest; if such improvement does come, I venture to express the hope that we may in the coming year meet more frequently than we have done in the past one, and that our meetings may be, as they should, the means of stimulating energy and enthusiasm amongst us, and I would urge upon all to make some little effort to a better attendance (to-day half our members are not present), and to make occasionally if required some self-sacrifice in order to attend, and to contribute from your individual stores of experience and knowledge for our mutual benefit. In Victoria we inaugurated at the beginning of this season a series of bi monthly meetings for the reading of and discussion after of matters professional, but this for lack of attendance fell through at the fourth meeting.

You all know the fate of our "Architects' Bill," more badly beaten than its predecessor. We have already discussed this question, and our decision is quite in accord with my own feelings that we should wait, as decided on Mr. Soule's proposition, and put ourselves in communication with our eastern brethren.

Since our last annual meeting, at which we patted ourselves on the back at our success in regulating, or being in a fair way to regulate, public competitions, we have passed through three. In the first—the Government Official Buildings, which fell to the lot of a Vancouver architect—happy proof of the honesty of Victoria architects and freedom from undue influence—and a happy instance of the satisfaction following the selection of professional arbitrators. Mr. Sorby, of our city, secured one of the five honors, with, to my way of thinking, a charming bit of design, most artistically executed, thoroughly English in character, the work of an artist. Next we have to record the competition for the Protestant Orphan Asylum, under conditions more or less framed by ourselves, and carrying a clause prohibiting any canvassing of the committee—a work brought to coapletion and recently opened—a competition that carried with it so far as I have heard no dissatisfaction. Of the third competition, the least said the better; it goes to show that all our self-congratulations last year were premature. I hope our action will prevent repetition.

About this time last year, at a Council meeting, some of your members formed themselves into a self-constituted committee, to frame by-laws for this city, and after some five or six meetings had been held, this too fell through—not because we were too busy to devote the time, but I fancy from an unexpressed feeling that our work, while voluntary, was superorogatory, and perhaps if completed would have been a thankless task; it certainly would have been valuable if worked out. It also, I think, grew so in magnitude as we worked at it that, without admitting it to each other, we shirked it.

In occupying this chair to-night, I am going to indulge in a little criticism of the past year's work in the buildings of this city. Of course, you can form your own opinion of my remarks, and after I have finished criticize them at your will.

There are few completed buildings in Victoria of the past year that will call for much more than a passing notice. A departure from the general run is seen in the Temple building offices of Messrs. Ward & Co., a red brick and terra cotta building that suffers from its close juxtaposition with its high neighbor, and is dwarfed by it. I would more like to feel with reference to it that the well designed and treated terra cotta detail was made for it, and not its façade for the detail. There is in some grilles to the ground floor windows some very good iron work.

The Davie block is another new block I would make a passing reference to. Some of you will remember the *Times*' criticisms, and the criticisms on such criticisms that followed, and the amusing reference to "Dog Latin" styles—Romanesque. To one who has studied Romanesque art in its native country such references will certainly be amusing. The term Romanesque as applied out here is a misnomer in every sense. The Five Sisters block was so called by the same authority when the designs for it were first seen. I do not like the trabeated architecture affected here by some of our architects in the use of roughly hewn stone; it looks coarse, especially when used in a third and fourth story; and the zinc shams, such as find place in this block, are I think to be condemned as untruthful and unconstructive. Better put up with plainer and simpler forms if economy has to be taken into account.

The new Protestant Orphans' Home, perched as it is on a hill, might have had a more effective outline than it has, and the money spent on brick decoration, which is not seen until close under the building, might have been devoted to carrying up the roof of the semi-circular portions of the front.

It remains to be seen what the two new ward school buildings will be when completed. There is a breadth of treatment about the North ward building that shows up effectually at present, if it is not going to be crushed in appearance by the roof.

I think that I may include the Board of Trade new building in this year's completion. I do not like it in hardly a single feature. I do not like to see a building, standing as it does, the end and flank to the sea approach to Victoria, as factory-like in its want of treatment as this is, and there are bits of eccentricity in the façade that seem to be simple indulgences as freaks of design—objectless. It is an error, I think, to put at such a height as is done here minute detail, and in the crowning feature of the cornice grotesqueness culminates in the intersecting ornaments—of tin—at the corners. The middle stage is decidedly weak in design, and the plan seems to me more of a puzzle than an economical arrangement, in its broken stairs and crooked passages, and is badly lighted in many places.

I was one of the Victoria members of our Association who attended last year's meeting in Vancouver, and in the company of your other vice-president made the most of our time in seeing that city—grown out of all recognition to me since taking it in my visit from India in the latter part of 1888. We paid considerable attention and went over some new buildings under construction—and this period of construction is, as you all know, the time when shams stand unveiled, and when true construction can be seen. We were both forcibly impressed with the difference in character of the work done in Victoria and that done in Vancouver. In Vancouver the buildings have a degree of solidity and truth in them that is sadly wanting in buildings in our Capital City; ours are only too often what I look on as mere match-box constructions. I think our architects should kick against it. I know where the difficulty comes in. Architect A, inclined to go in for something better than mere lath and plaster partition walls, goes in for brick in accordance with good by-law construction and the credit of his profession; he would soon be put out of the field by Z, perhaps a needy self-styled architect, who, creeping in behind A, informs A's client that he, Z, can save at least $1000 of cost, said client being left entirely in the dark as to where and how the so-called saving comes in. To my mind A should carefully and thoroughly urge upon his client the question of stability and solidity as against "jerry work," and then only on his client accepting responsibility, go in in opposition to Z, and fight him with his own weapons. I fear, though, that some of our clients, if reports are true, play you off one against the other and then take the cheapest; some of you sell your work Dutch auction bidding. In my three years of residence in Victoria, I have seen such construction as I would not have ventured on, and yet in my work and practice in India I have done work in construction much bolder than my peers. The work I refer to as done in Victoria is not healthy work of construction, and I think it regrettable that in the Capital of the province our architects should feel impelled to do such work—that such work should be looked on as a necessity. Men as owners of such work cannot, I think, have had them built as investments—only to sell—and even then false economy.

I was very much surprised only the other day to learn that the Building Inspector in Victoria has it in his power to alter a detail of construction in an architect's design. I should protest against such interference in the construction details in a competent architect's work; I mean one who may be reasonably credited with possessing sufficient knowledge of construction. I think that with good by-laws and a good Inspector to see them honestly carried out, interference with an architect's construction would not be called for, and with good by-laws, not restrictive ones, and a resolute enforcement of them, such buildings as I have commented on would not be perpetrated.

It is within my province to-day to enter my protest against the recent action of the bricklayers of this city in their striking against the appointment of a clerk of works not belonging to their organization, appointed for the municipal supervision of their work by the municipal authorities, and I anticipate that you are all of one mind. If such action and claim as they made were once acceded to, on such a plaint as was theirs, it would place us architects quite at their dictation.

Before we meet again, gentlemen, let us hope that things may improve with us all, and that we will be all busy men as now too many of us are idle men.

The next annual meeting of the society was fixed for New Westminster, on the first Friday in November, 1894.

Red slate is of recent discovery. The most beautiful of its class, it ranks among the costliest material in use for constructional purposes. In the northern part of Washington County, N. Y., within a circle less than fifteen miles in diameter, are said to be the only red slate quarries ever found. There are two parallel veins about five miles apart; the one known as the Granville vein being best adapted for roofing purposes; the other, in Hatch district, and of softer quality, can be sawed into floor tiles and house trimmings.

A discovery for hanging paper on damp walls is being put to a practical test in Germany. It consists of coating a lining-paper on one side with a solution of shellac spirit, of somewhat greater consistency than the ordinary French polish, and then hanging it with the side thus treated to the damp wall. The paper-hanging is then performed in the usual manner with paste. Any other resin that is equally soluble in spirits may be used in place of the shellac. According to the representations, this process is found equally effective in preventing the penetration of dampness.

CANADIAN CITY ENGINEERS.

VII.

ROBERT SURTEES, City Engineer of Ottawa, Ont., was born at Ravensworth, Yorkshire, England, March 3rd, 1835. He served his apprenticeship with the late George Mason, a well known civil engineer in Darlington. At the age of 21 he came to Canada, and first settled in the city of Hamilton, where he acted as Assistant City Engineer for four years, when he removed to New Edinburgh, a village now embraced within the city of Ottawa, where he established himself as an Engineer and Architect.

During his fifteen years residence there he designed and had charge of many important public works, amongst them the Protestant Hospital and the Carleton County Court House in the city of Ottawa. He was engineer of the town of Peterboro', Ont., and city of Hull, P. Q., waterworks, and acted as consulting engineer for a number of municipal corporation drainage and water works schemes.

In 1875 he accepted the position of engineer for the city of Ottawa, and under his direction and supervision some important works were carried out, such as the construction of the main sewer, and the enlargement of the water works system, the former costing half a million dollars and three years labor to complete, and the latter work entailing the expenditure of a similar amount. These works may be classed as amongst the finest in the Dominion.

Mr. Surtees is a member of the Canadian and American Society of Civil Engineers, as well of the American Water Works Association.

Politically he has always been a Conservative. In religion he is a member of the Church of England and is thoroughly evangelical in his views. He married in Hamilton and has a grown up family of two daughters and four sons.

ROBERT SURTEES, CITY ENGINEER, OTTAWA.

A STUDY IN LIME.

LIME constitutes so large a portion of the building material used in this country, says V. B. Grinnell, in the *Painters' Magazine*, that it seems to me that every builder and decorator should be familiar with its nature, composition, impurities and reaction upon the elements of organized substances coming in contact with it. "Lime is ranked with the alkaline earths, and is never found pure in its native state, but combined with carbonic acid in marble, calcerous spar, limestone and shells, and with sulphuric acid in gypsum, and phosphoric acid in the bones of animals." When lime is made by burning the native carbonate or limestone in kilns it is usually impure, containing alumina, silica, sesquioxide of iron, magnesia, oxide of manganese, clay, &c. The carbonic acid is expelled by the heat in the kiln, but when cool and exposed to the air it absorbs moisture and carbonic acid, and crumbles into powder, and becomes air-slacked lime. When water is added to the fresh lime heat is evolved, the stone cracks and powders, forming hydrate of lime. Lime is so sparingly soluble in water that it takes 700 times its weight in water to completely dissolve it. It acts upon vegetable colors like an alkali. Lime has many incompatibles, among which we may name: "All acids, all metallic acidulous and ammoniacal salts, borates, alkaline carbonates, and astringent vegetable infusions." In other words, they cannot exist together in solution without natural decomposition, and combining their acids, forming calcium salts.

The painter and decorator finds a large portion of his work upon plastered walls, and to do it intelligently he must understand the composition of the wall and the nature of the materials used in its construction, and the effect which they may have upon the various materials which he may be called upon to use in the course of his work. If he is not posted in this respect, he goes at his task in the dark, and must not be surprised if he meets with occasional disappointment and failure. We know that the lime in the well may contain impurities, and that the sand mixed with it may contain clay, and that clay may contain sulphur. The sand may be mixed with iron pyrites, sulphate of lime, sulphate of barytes, magnesia, &c. In the great crushing process which ground the mighty rocks to sand, all the minerals which they contained went in. Who can tell what they were or what has been added since the sand has been drifting from place to place? Who knows what salts will be formed when the impurities are set free and brought together by the water used in mixing the lime and sand into mortar? The heat in the lime in drying may prevent much that would otherwise happen: but in after years, when the plaster has been long or frequently wet, the sulphur and magnesia coming in contact may produce sulphate of magnesia (espom salt). This salt contains more than 51 per cent. of the water of crystalization, and often has very much to do keeping walls damp and in forming crystaline incrustations upon the surface, especially upon brick walls. This salt is completely decomposed by fresh lime, but the lime in plaster, which has been long water-soaked, seems to have become sufficiently inert to admit of the formation of the salt in question. This salt is also decomposed by "potassa and soda, and their carbonates by baryta and stronia, and their soluble salts;" but the trouble is to apply any of these decomposing agents to the source of supply in the interior of the brick or mortar of a brick or plastered wall. We may decompose the crystal upon the surface, but the dampness inside will continue to throw out more of the salt. We sometimes sufficiently decompose it near the surface, to make it possible to check its further advance. First soak the wall with the decomposing agent, and after it is dry apply a coat of waterproof paint or gum. For the outside the dry hot weather of summer is the best, because the hot weather will dry the surface after the decomposing agent has been applied.

An example of the rapid formation of the crystals of this salt came under my observation two years ago in a basement. A bank of clay had been cut down and a plastered wall made near to it. Subsequently the basement was flooded with water, which stood for several days, thoroughly soaking the wall. Within a few weeks I discovered crystals upon the surface of the wall; they continued to increase until several square yards of the wall were covered, in places half an inch in thickness. The product was unmistakably epsom salts. I found, upon examination, that the wall was still wet, and that the space between the wall and the bank had been filled with earth, which had been washed from the top of the bank, which I found still damp. As an experiment, a small portion of the wall was dried by artificial heat, and then kept wet for a day by frequent applications of a strong solution of carbonate of soda. The plaster was then dried and given two coats of orange shellac. At the end of eighteen months no more crystal had formed upon the place which had been treated. The crystals of this salt upon brick walls are frequently called saltpetre; but I am at a loss to know why, because the taste and form of crystals in the two salts are so much unlike. Saltpeter is found in old plaster rubbish, in combination with lime and common salt; but in this combination it seems to be inert. Saltpetre has a sharp, cooling, and slightly bitterish taste, and its crystals are long, striated, semi-transparent six-sided prisms. Epsom salt crystalizes in four-sided prisms, is colorless and transparent, of bitter, nauceous, saline taste.

The Engineering Society of the School of Practical Science, Toronto, has decided to establish a monthly paper.

The new high school building recently erected at Niagara Falls, Ont., was formally opened on the 8th inst. by the Minister of Education. The building is erected in Wesley Park, and is surrounded by seven acres of ground. The building and site cost about $30,000.

A representative of the National Wall Paper Company of America was in Ottawa recently for the purpose of inducing the Customs Department, in making valuation of imported wall papers, to allow for a discount of 20 per cent. which the company offers to all dealers who use its goods exclusively.

The new hotel Frontenac, erected by the Canadian Pacific Railway at Quebec, was opened to the public on the 18th of December. The building contains 170 bed rooms, some of which are 310 feet above the level of the St. Lawrence. The building occupies a magnificent site, affording views up and down the river, of the Isle of Orleans, and of the Laurentian range of mountains. It is designed in the old chateau style, the decorations and furniture being of 16th century character. Mr Bruce Price, of New York, was the architect.

THE BUILDINGS OF THE DOMINION.

By G. F. Stalker.

To what extent and in what manner the government is justified in encouraging by substantial aid, the development of art depends upon a variety of circumstances. The possession, however, of galleries of art treasures and of fine buildings is an unmistakeable evidence of national culture and progress; and no country having any pretension to greatness can afford to be without them. The balance sheet of the finance minister is, after all, only a temporary index of national solvency. We must look into a different ledger for the indelible marks which show the onward or backward movement of the people. But the finance minister and every other minister, can do a vast amount to foster and develop such thoughts and feelings as will ineffably impress themselves on the national character, and find expression in works of art which will be an indication to future generations of our standing as a people.

The ministers of the crown in this country are the chosen leaders of the people, and they like to be spoken of as such. But they are, in many instances, only the followers of public sentiment. Ideas and schemes, which on the face of them have the stamp of necessity (sometimes of urgency), are put on one side because there has been no public demand for them and so much valuable time is wasted in weary waiting for the great unwieldy mass of the people to meet together, formulate their ideas, and submit their wishes to those in authority. All this seems just the reverse of what it ought to be. The wise leaders, whose names have come down to us, have been men who, being in advance of their time, have educated the people up to their ideas, and legislated and acted without the necessity of ever-recurring agitation and turmoil.

At present we want one or more of the ministers to strike out and take the lead in national art matters. The course is perfectly clear, and whoever steps into it will have the satisfaction of knowing that the laurels which he will gain will not be plucked from the brow of any of his contemporaries, nor from the chaplet of any of his predecessors.

It is, of course, freely admitted that there are difficulties in the way, the chief one being that we belong to a somewhat utilitarian race. The British people have never been too lavish in expending money on "mere works of art," and it has taken a long time to bring them to acknowledge the refining influences of the beautiful and pure in art, upon the national character. But this is admitted now, and leading men throughout the empire lose no opportunity of impressing this truth upon us. In fact, if we look at the matter fairly, the encouragement of art by the national government is really utilitarian in its effect. The national advancement and refinement are a *quid pro quo* for the national expenditure.

A slight indication of the way the wind is blowing was given during the last session of the Dominion Parliament. While the estimates were being discussed the Minister of Interior asked for a beggarly sum of one or two thousand dollars for the annual expenses of the National Gallery, when from an unexpected quarter a loud complaint was raised because the sum asked was not twenty or thirty thousand, which would have been as readily granted as the smaller sum. The fact that the complaint met with the general approval of the House is sufficient to show that the time has gone by when ministers need be afraid to ask for the expenditure of public money for art purposes; and it must be with satisfaction that every man of education and good sense will regard this fact.

But it must not be supposed in speaking of art, that painting and sculpture only are referred to. Architects need not take a second place to their brothers of the brush and chisel in the beneficient effects on the public mind which are produced by their own branch of art. On the contrary its place in the trio of the fine arts has always been, and will ever be the first. And while, as an art, it exercises its refining and ennobling influences on the mind, it is practically interwoven with every phase of human existence.

On this account and because it would be impossible to conduct the business of the country without necessary and adequate building accommodation, architecture has received a fair amount of encouragement at the hands of the government. No fault can be found with the different governments so far as providing buildings when and where they have been found necessary. But the system which was adopted at the birth of the Dominion and which was both necessary and suitable for that time has nothing to recommend its continuance at the present. When the Dominion came into existence there were very few architects in the country and comparatively no very great demand for them. Since then, however, the country has made rapid strides and has developed in every direction to an abnormal extent. With this growth has come the demand for a better class of building, and architects have come into the country and grown up in it to supply the demand; so that the larger cities particularly are well provided with buildings of a high order, and give unmistakeable evidence that we have in our Dominion as capable a body of architects as are to be found in any other country at the present day.

The government has no need, therefore, to restrict itself for its architecture to the abilities and services of one man, as was necessary and suitable thirty years ago. The system which we followed at Confederation was the best system for a young country; but we shall be doing a wise thing when we follow the example of Britain and other countries, and give opportunities to more than one architect to display their architectural abilities.

In quite recent times there have been a great many large public buildings erected in England, such as the Foreign Offices, the Law Courts, the Natural History Museum, the Admiralty Offices, etc., etc. In every case the designs for these buildings were chosen either by public or limited competitions. The object the British Government had in view in these competitions was, not only to obtain the best designs, but to give to architects generally an incentive to put forth their best efforts and to bring into prominence the talents of some who would otherwise have remained unknown.

It is impossible to overestimate the benefits to the profession and to architecture in England, which have resulted from these competitions. The influence of the designs that were submitted and that remained for many weeks on public exhibition has completely revolutionized architecture in England. At the beginning of the present century and until about fifty years ago architecture in England was at a very low ebb. Now there is no country in which buildings are erected on a grander scale, of more beautiful design, or where so much attention is given to architectural principles and detail.

To say that this has been brought about by the system of having competitive designs for government and other buildings would be to claim a great deal too much. But no one can deny that this has been one of the most potent factors in producing the change. If such a system were to be adopted in Canada there is no doubt that the effect upon the architecture of the country would be beneficial, but it would give national encouragement to architecture without incurring any further charge upon the Dominion exchequer than is incurred now. The cost of maintaining the architects department in connection with the government amounts to more that five per cent. of the annual value of the buildings erected. The change would therefore involve no financial loss, but rather a gain to the country. It is not, however, for this reason that the question is here raised. Neither is it from any desire to find fault with the present government architect or to speak disparaingly of his ability. If the present system is to remain unchanged it would be no easy matter to find, in the whole Dominion, a man better qualified for his position. But the circumstances which rendered such an office necessary no longer exist.

The buildings erected by the Dominion Government are chiefly post offices, custom houses, government offices and drill halls, and though there is not much variety in the classes of buildings, the location and local requirements introduce elements sufficient to require considerable variety of treatment. But the most versatile architect becomes in the course of time liable to repeat himself; he may even become stereotyped in his versatility. We cannot therefore, look for much progress in the architecture of our national buildings, when we continue through a long series of years to engage the services of only one man. But we are certainly running the risk of remaining at a standstill in this respect; and to do so is to retrograde.

But if it be a wise thing for the government to secure by competition the best designs from the best architects in the country for our public buildings, it would be equally unwise to abolish absolutely the office of government architect, and here again we might imitate the practice of the motherland. In all public buildings there are changes made as time goes on. And so, when any building has been completed according to the architects design, the plans are deposited with the government architect, who, with a sufficient staff of capable assistants, will look after any future changes which may be found necessary.

As already stated, the course is open for any Minister of the Crown to distinguish himself by lifting our national art up to a higher level than it occupies now. And the foregoing is humbly submitted as an outline of a system which could easily be adopted in regard to our public buildings, and one which would give great satisfaction to the profession generally, as well as being of inestimable and lasting benefit to the country at large.

NEW YORK CITY HALL COMPETITION.

On the 20th of December, the Advisory Board of Architects in the above competition presented their report, in which they announced the selection from 134 designs submitted of numbers 13, 23, 28, 35, 107 and 113 as the six which most nearly meet the requirements. The final selection will be made from these six selected designs at the close of the present month, and the names of the successful competitors announced.

The oldest school building in Montreal, situated at the corner of Cote and Lagauchetiere streets, has been sold for the sum of $20,000, for manufacturing purposes.

The Arts and Crafts Association of Hamilton, has been organized at Hamilton, Ont., local artists and architects being among the chief promoters. The object sought to be attained is to foster local talent and assist in bringing the work of artists before the public. The organization meeting in the Hamilton Art School was well attended. Mr. E. W. Morrison was appointed secretary of the Association, the election of officers being deferred to a subsequent meeting.

CANADIAN vs. FOREIGN CEMENT.

— Quebec, December 23, 1893.

Editor Canadian Architect and Builder.

Sir,—In your last issue, Dec., '93, page 121, you say in relation to Canadian cement, alluding to the Soulanges Canal: "This is the first instance as far as we are aware in which imported cement has been used in Canadian public works of this character."

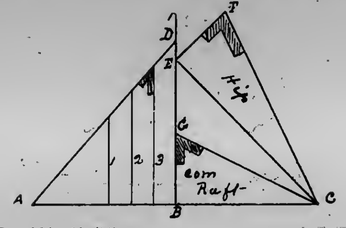
I would inform you that some $80,000 worth of imported Portland cement is said to have been used in the new docks, Quebec, and you are perfectly right in deploring the ignoring of our Canadian industries.

C. Baillairgé,
City Engineer, Quebec.

ROOF DIAGRAM.

Editor Canadian Architect and Builder.

Sir,—I herewith enclose you a practical diagram on hip roofing which you may be pleased to publish for the benefit of your readers:



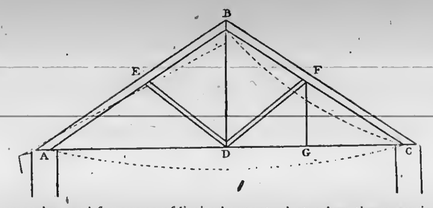
A C—width of building.
C G and B D—length of common rafter.
E F and B G—rise of roof.
B C and B E—run of common rafter.
A D and C F—length of hip.
1 2 and 3—exact length and bevels of jack rafters.

A. B. Campbell,
Brandon, Man.

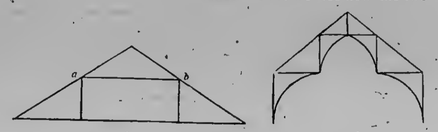
ROOF TRUSSES.

The action of trusses on walls, and their weight and thrust, is one of the important matters in building that should be carefully studied and understood by all builders. In designing a truss for any kind of building there are several factors to be provided for, which the following article by Mr. I. P. Hicks, in the *National Builder*, fully illustrates:

Let A B, C B (Fig. 1) be two rafters, placed on walls at A and C, and meeting in a ridge B. Even by their own weight, and much more when loaded, these rafters would have a tendency to spread outward at A and C, and to sink at B. If this tendency be restrained by a tie established betwixt A and C, and if A B, B C be perfectly rigid, and the tie A C incapable of extension, B will become a fixed point. This, then, is the ordinary couple-roof, in which the tie A C is a third piece of timber; and which



may be used for spans of limited extent; but when the span is so great that the tie A C tends to bend downwards or sag, by reason of its length, then the conditions of stability obviously become impaired. Now, if from the point B a string or tie be let down and attached to the middle D, of A C, it will evidently be impossible for A C to bend downwards so long as A B, B C remain of the same length; D, therefore, like B, will become a fixed point, if the tie B D be incapable of extension. But the span may be increased, or the size of the rafters A B, C D be diminished, until the latter also have a tendency to sag; and to prevent this, pieces D F, D F are introduced, extending from the fixed point D to the middle of each rafter, and establishing F and E as fixed points also, so long as D E, D F remain unaltered in length. Adopting the ordinary meaning of the verb "to truss," as expressing to tie up (and there seems to be no reason why we should seek further for the etymology), we truss or tie up the point D, and the frame A B C is a trussed frame. In like manner, F being established as a fixed point, G is trussed to it. In every trussed frame there must obviously be one series of the component parts in a state of compression, and the other in a state of extension. The functions of the former can only be filled by pieces which are rigid, while the place of the latter may be supplied by strings. In the diameter, the pieces A B, C B are compressed, and A C, D B are extended; yet in general the tie D B is called a *king-post*, a term which conveys an altogether erroneous idea of its duties. Thus we see how the two



principal rafters, by their being incapable of extension, serve, through the means of the king-post, to establish a fixed point in the center of the void spanned by the roof, which again becomes the *point d'appui* of the struts, which at the same time prevent the rafters from bending, and serve in the establishing of other fixed points; and the combination of these pieces is called a king-post roof.

It is sometimes, however, inconvenient to have the center of the space occupied by this king-post, especially where it is necessary to have apartments in the roof. In such a case recourse is had to a different manner of trussing. Two suspending posts are used, and a forth element is introduced, namely, the *straining beam a b* (Fig. 2), extending between the posts. The principle of trussing is the same. The rafters are compressed, the straining beam is compressed, and the tie-beam and posts, the latter now called *queen posts*, are in a state of tension.

In some roofs, for the sake of effect, the tie-beam does not stretch across between the feet of the principals, but is interrupted. In point of fact, although occupying the place of it, it does not fill the office of a tie-beam, but acts merely as a bracket attached to the wall (Fig. 3). It is then called a *hammer-beam*.

MANUFACTURES AND MATERIALS

The firm of Lomer & Rose, metal merchants, Montreal, has been dissolved.

A quarry of black granite of good quality, is reported to have been discovered at Bocabec, N. S.

A Canadian patent, No. 44,650, has been granted to H. W. Kincaid, of Athens, Ont., for a metallic shingle.

The stone which is to be used in the construction of the Soulanges Canal will be obtained from quarries at Rockland, Que.

The Canadian Cut Nail Association decided at a recent meeting, not to make any change in prices. The Wire Nail Manufacturers decided to make a five per cent. reduction in the discount allowed the trade.

A vitrified brick manufactured by the Hamilton and Toronto Sewer Pipe Co., was recently tested, and after having been immersed in water for three days, showed an increase in weight of only 4-9ths. of an ounce, the original weight being 7 pounds.

Awards were granted to exhibits at the World's Fair by the following Canadian firms: New Rockland Quarry Co., Rockland, Que., for slate sink, etc.; P. W. Ellis & Co., Toronto, veined marble; the Rathbun Co., Deseronto, cements; J. R. Ward, Grenville, Que., marbles.

The St. Johns Stone Chinaware Company, of St. Johns, Que., has been reorganized with Messrs. Laviolette and Leduc of Montreal, as president and vice-president and Mr. Alex. Maedonald as managing director. The re-building of the company's factory at St. Johns is being rapidly pushed forward.

Messrs. Wm. Gibson, Benton, N. B., Robert A. Stuart and J. M. Hanson, of St. Andrews, N. B., have entered into partnership to quarry, manufacture and deal in granite and stone, the firm name being Gibson, Stuart & Hanson. The term of partnership is from the first of December, 1893, to the first of December, 1903.

It is reported that under the management of T. F. Pharoah, the slate quarry near Danville, Que., is being successfully operated, upwards of 50 men being employed. There are some benches of pure slate 30 feet thick, and single pieces of seven to twelve tons weight are quarried. The material is worked into blackboards, flooring, roofing, etc.

The first annual meeting of the shareholders of the LaPrairie Press Brick and Terra Cotta Company, was held at the offices of the company, 118 Peter street, Montreal, on the 16th of December, when a very satisfactory statement of affairs was presented, and satisfaction was expressed with the result of the manufacturing thus far done. It has been decided to invest some $25,000 in additional plant, the intention being to manufacture during the present year about 10,000,000 common and pressed bricks. The following board of directors have been appointed:—A. A. Ayer, J. W. R. Brunnett, Peter Lyall, John McKergow, J. W. Tester, A. D. Taylor and Hugh Cameron. At a meeting of the directors, A. A. Ayer, was elected president, J. W. R. Brunnett, vice-president, and T. A. Morrison, secretary-treasurer.

THE WINTER CARNIVAL.
THE ICE PALACE.

QUEBEC IN 1894.

By Chas. Baillairge.

THE old-fashioned city of over 25 years ago has put off many of its characteristic traits and donned quite a new and comparatively modern physiognomy.

The six city gates have either disappeared *in toto*, as with the three facing on the St. Charles and the St. Lawrence, where, on account of the precipitousness of the cliff, the unnecessary walls have been lowered to allow of being seen over; thus giving to tourists on entering the city from the C.P.R. a splendid view of the port—one of the finest and most extensive in the world—or have been remodelled, rebuilt in a way to be less offensive to the outlying wards, which had come to view the barriers as lines of social distinction between themselves and the would-be aristos within.

The stratagetic curves of the old approaches to the city walls having lost their prestige under the high and far flying missiles of war of modern times, the sinuosities outside of the city gates are now replaced by straight and unbroken lines of streets, while the crenelated tops of the new gates are there to remind us of our ancient military glory.

The "Grande Allée," extending a mile beyond the city proper, has had its width not less than doubled, and along its southern side we have the splendid new "Drill Hall," built after the designs of M. M. Taché & Fuller, architects, but laid at a level fully five feet lower than it should have been to be properly seen from the St. Louis road.

Nearly opposite the Drill Hall is the Short and Wallick monument, designed and executed by our talented Canadian artist, Hebert, who also carved the "Indian Group" over the fountain opposite the tower of the Parliament buildings, but which is singularly marred in its effect by being set at a level about three feet lower than it should be. The new Government architect, Mr. Charest, should see to this, and that there be erected without further delay, and as much more pressing than the enclosure walls around the grounds, a porchway such that a carriage may drive under and persons be thus enabled to enter the building under cover, instead of, as in the case of the last bill, having to hold an umbrella over every gentleman's and lady's head as they successively entered the buildings with garments thoroughly drenched by the storm.

The portico alluded to could be most easily and æsthetically erected opposite the main or central tower by making each of the two angle piers of the porch a group of four columns like those on the opposite side, bringing forward the present entablature and completing the sides.

The most ungainly facade along the river side of the Grande Allée is that of the skating rink which architect Staveley had made quite a fine feature of when on the opposite side of the street, but which from motives of economy, he was prevented from having carried out on its previous lines when moved to its present site to clear the ground fronting on the new Parliament Buildings. Ranges of fine dwelling houses have sprung up all along the thoroughfare, and of various design, under architects Raymond, Berlinguet, Peachy, Tanguay, Bussieres, Bernier, Talbot, and others, with, further on, Stent and Laver's Female (old military) Orphan Asylum, Le Court's Protestant Home, with the St. Bridget's Asylum and many fine residences on the opposite side, including the so-called Langélier block by Berlinguet, but where the site is far too straitened for the size of edifice—too many trumpery finials about its roof, and too much crowding of the bays and oriels on the central corps and portico. Dr. Verge's dwelling is amongst others worthy of remark.

The principal architectural feature along this thoroughfare is, of course, the Parliament Buildings already incidentally alluded to, the architects of which were M. M. Gauvreau, Taché, Derome, Cousin, Gauvin and Lesage; but that an article like the present, published in such a journal, may have its full utility, as a lesson to all concerned and to architects and the public in general to prevent the repetition of such a costly blunder, it will be seen that the building all around the 300 feet quadrangle should have been 60 feet in depth instead of 50 feet, making rooms instead of guts of the spaces on either side the central corridor, and adding 33 per cent. to the available depth for stairs instead of the break-neck things they are.

The building, of which the exterior is well enough proportioned and the architectural features not unæsthetic, though no building can be truly grand which, like this, has not a central feature—a dome for instance, a spire or a tower rising from a structure in its midst, and around which the outer portions of the edifice may cluster and rise the one above the other ("pyramider") an expression which can hardly be rendered in the sister language except by the word 'to tower,' but which is exemplified in our new Frontenac Hotel, by Bruce Price, of New-York, architect, with the exception that the roof over the entrance gate should have been made just one storey higher, and thus have hidden at the same time the upper rear corner of the main building not intended to be seen, and which protrudes itself most ungraciously into sight.

Now it will hardly be credited that while the splendid cut stone enclosure wall and lofty ornamental wrought and cast iron railing around the Marine Hospital, Quebec, designed by the writer, costs but $13.00 per foot lineal complete *in situ*, the mere coping alone of the more than 6,000 feet lineal of walls surrounding the Parliament grounds, with its underlying plinth course and dwarf foundation to the rock, and exclusive of cement, has been paid for at the enormous rate of $29.50 per foot lineal, exclusive of iron work, thus swelling its cost to four times the price of the wall alluded to, and amounting to the astounding sum of $200,000 or more.

The workmanship, it is necessary to say, is very fine, and the 12-foot granite monoliths superb; but I do not know at whose door the fault is to be laid of giving the separating pillars a projection on all sides of only 1½ in., which should have been at least from 3 to 4½ inches to render the work architecturally effective, making it deeply to be regretted that so much of the public money has been expended on a work which in proper hands could have been rendered an acceptable feature of the general design at much less than half the cost.

Persons who have not visited the city within the last fifteen years must be reminded that we have a terrace which is well worth seeing, and of which Princess Louise and the Marquis of Lorne, while performing the ceremony of throwing it open to the public in 1879, said to Mr. Baillairgé, engineer of the structure, while cordially congratulating him and shaking him by the hand, "this is the finest promenade in the world," and so I believe it may be considered, not only on account of its length, though less than that of St. Germain in France, but hanging as it does, so to say, from the face of the cliff at the sensational height of 182 feet above mean tide level of the St. Lawrence.

This terrace, erected by the city entirely of wood at the time, and at a cost of only $20,000, from motives of economy, has since been walled in on the river side at the expense of the Federal Government at a cost of over $60,000, said wall forming portions of the enceinte fortification of the city, and which had been destroyed by the landslide of 1841; and what it will now behove us soon to do, is to replace the perishable structure by stone and iron, brick and asphalt: cross walls at distances of sixty feet apart being necessary not only for floor supporting purposes, but to counteract the ever-present, ever-active tendency of all such side-hill structures to move forward and downward by the effect of earth and frost pressure from the rear. The space from wall to wall would be spanned by sixty ft. built plate girders with intervening supporting columns; iron joists laid across these at say three ft. centres, ½ brick archings between them, and concrete and asphalt over all, estimated to cost another $60,000.

The new Post Office, but which can hardly be called so now, should evidently have had a proper architectural facade towards the St. Lawrence, and had its upper floor windows been made of proper height, the extra course or two of masonry taken from the space above would have corrected the top heaviness of the structure.

The new Court House is of course a great improvement in size and style as compared with the old building, but the combined areas of openings is considerably beyond what it should be in relation to that of walls. The architects of these two buildings were, of course, some one or more of the Government quintet already named.

I have alluded incidentally to the new hotel, and would state that the architect, Mr. Bruce Price, of the United States, has, in my opinion, been guilty of a serious omission in not providing in any way for escape in case of fire, nor for a few outside iron balconies where one could sit and smoke and have a cup of coffee while enjoying the view and music. In other respects the building is a fine structure, and its architecture, its plan, its site, well suited to the fortress-like surroundings.

We have designs at hand for a new City Hall on the Jesuits' lot, and this is the lot it should be built on; as, though it may not appear to be quite centrally situated, since St. Sauveur has been annexed, there is no doubt that any extension of the city will now occur towards Hedlyville, and make it in reality the central site required.

St. John suburbs, under architect Peachy, has erected a spacious and costly (say $200,000) new cathedral instead of that destroyed by fire in 1881, but the diameter of its spire is by several feet less than it should have been.

In the lower town Hon. P. Garneau has erected, under Contractor Parent, a splendid new $100,000 stone structure, but my friend Tanguay, the architect, has been guilty of a freak, which cannot be called a license, and would not be tolerated anywhere—that of running his mullion or dividing column right up to the very keystone of the upper or attic window instead of cutting it short at the impost level and throwing the space above into two sub arches and a central panel or spandrel.

St. Roch's has now become, so to say, the commercial portion of the city, and the merchants and citizens of that locality have erected some very fine buildings under Mr. Raymond at the corner of Crown and St. Joseph streets, others by architects Talbot, Bussieres, Bernier, Vallée and Dussault—one of the finest by Peachy, for Labibertee, the furrier. The stateliest of all, some six tall stories in height, and of solid monolithic granite piers, and polished granite columns for Paquet, under his architects and builders, M. M. Charest and Bertrand.

New streets have been opened in the lower town, as Dalhousie and St. André, facing on the St. Lawrence and harbor works of the River St. Charles. Others have been widened; some prolonged, as St. Paul street to St. André, St. John 'St. Within, Fabrique. Ann in the upper town have been widened, St. Claire and Salaberry in St. John Ward.

D'Youville street, by Kent Gate, eases off the grade from St. Lewis to St. John's wards, and Negresse Hill, that from John to Jacques Cartier wards, while a new grade is being run from Grande Allée to the Citadel Heights at the old French fortifications, where a splendid view of the harbor can be had, and of a dozen parishes around and the main road reached again by a loop line without leaving one's carriage.

It is only lately we have enacted that henceforth all streets be at least 66 ft. in width, and lots 100 ft. deep, after my showing on the occasion of each of our monster fires of 1845, 1866 and 1881, etc., that their extent was due to nothing but want of depth in our heretofore 60 ft. lots, where if you build a house 30 ft. in depth, stables or an outhouse another 20 ft., there remains but 10 ft. between the two, with 30 feet streets between the blocks.

We now have in addition to the St. Louis and Frontenac hotels, the Royal Albion; and the Florence House under B. Trudelle, is also one of the most central and best patronized hotels in the city, with lines of busses to drive you any and everywhere; and the city having just opened a new line of communication by Mount Pleasant into St. Ours street, I would advise tourists wishing to enjoy a splendid view of the valley of the St. Charles to go out by Grande Allée, down Salaberry, get out at the steep part of the new hill, enjoying the view as you go down, resume your carriage at Arago street level, and then do St. Sauveur and St. Rochs, returning to the Frontenac or Florence by Abraham Hill and St. John street within or without.

The old wooden stairways between the upper and lower wards of the city have been replaced by elegant and costly new structures of cast and wrought iron, as at St. Claire and St. Augustin streets, and more recently at Buade and Champlain streets, with others to follow, as from the St. Charles battery to St. James street, and maybe from the remote extremity of Dufferin Terrace to Champlain street, while a new hill is contemplated from the Cove field to Cap. Blanc, thus saving a two miles' circuit to reach it by the brigade in case of fire.

Other alterations have obtained by which we have rechristened many of our streets, which bore duplicate, triplicate, and even quadruplicate names. We had, for instance, not less than four "St. Peter's," four "St. Francis'," three "St. Joseph's," etc., which were fruitful of many errors and inconveniences. They are now called by names dear to memories gone by: De Brébœuf, Garneau, Ferland, Christie, McMahon, O'Connell, Colbert, Chenier, *et al*, while a host of St. Sauveur saints have kindly stepped aside and been replaced by names less suggestive of prayers, pilgrims and poverty, and more of battles, bacon and business, as Kiroue, Fiset, Durocher, Racine, Charest, Charlevoix, Elgin, d'Youville, Hebert, Lalemant, Lansdowne, Colomb, Cartier, Montcalm, Wolfe and others.

Quebec is admittedly the best electro-lit city in America. It has a fine water power both for fire and domestic purposes under a head of 486 ft. from Lorette to mean tide level of the St. Lawrence. We have just completed under architect Peachy a splendid new fire station in Dorchester street; another new one in St. Sauveur by architect Cousin, is also under way, while still another is having its foundation laid in Lower Town near the Custom House—nine in all—and while danger from fire is thereby combatted on the one hand, all anxiety as to proper sanitation is fully provided against by our new quarantine system at the Palais, our costly steam disinfecting apparatus and our splendid new Hotel Dieu Hospital just erected under architect Tanguay, at a cost of a third of a million of dollars in Palace ward.

There is, however, one important thing we can not as yet boast of, and that is of the improved character of many of our streets. A million of dollars would be necessary to pave our hills and business thoroughfares with solid granite, and we can not afford such an outlay; though I call it false economy.

Our places of worship for all denominations are numerous and spacious, St. Mathews having recently been rebuilt by Staveley, and the Seminary Chapel by Peachy, but of which the inner galleries must be lowered in front or the interior made a failure.

Our educational status is high, with Laval in our midst; our poor well cared for by the Grey Nuns (Sisters of Charity); our too loving ones by the Asylum of the Good Shepherd; the waifs at the Sacre Cœur; and close at hand is the Beauport Asylum for all our mentally afflicted.

In addition to the Grand Trunk and Intercolonial railways, we now have communication with the remainder of the world around us by the Quebec Central, the C.P.R., the Q. & L. S. J. Railway, and the Quebec, Montmorency and Charlevoix; and the six companies should agree during our proposed carnival of February next to bring the people of our sister cities here to see the progress we have made. The new Frontenac Hotel, costing nearly a million of dollars, and of which the dining-room tapestry alone is valued at over $3,000, will be opened for the occasion, and a splendid reception tendered our guests in the new palace, and what between sleighing, coasting, snow-shoeing, curling, skating and other fun, a drive to the source of electric light supply at Montmorency Falls and mammoth ice cones of the Montmorency, a view of our ice palaces and statues and of the proposed 150 ft. pyramid of beauty over the illuminated fountain at the Place d'Armes, together with other attractions, such as ice-boating on the St. Lawrence and St. Charles, a good time may be anticipated by all our visitors, whom our mayor, Mr. Fremont, M.P., Senator Hearn and other city aldermen and councillors, and in a word all our citizens, will right royally welcome and endeavor to amuse and make happy to the fullest extent of their power. The new Palace Hotel of itself is well worth the trouble and expense of coming to see, and old Stadacona, even without the additional fun and attractions of a winter carnival, in which Montreal is to join us with several thousand of its snow-shoers, skaters, curlers and the crowds of other athletes who have promised to add to the festivities of the occasion.

And should the St. Lawrence be frozen over for the occasion, and our trees be decked as they generally are at such a season in snow crystals reflecting the component colors of the sunbeam and electric light, the millions of ruby, emerald, sapphire, topaz and diamond hues will enhance the fairy-like nature of the scene.

CANADIAN CONTRACTOR'S HAND-BOOK

Our attention has recently been called to errors in the above book. In the wages table on page 71, $14.96 is given as the wages for 66½ hours work at 21 cents per hour; the amount should be $13.96. On the same page $13.07 is given as the amount of wages for 67 hours at 21 cents per hour; the amount should be $14.07. The algebraic formulae on page 49 is in part incorrect; it should appear as follows:

4. $(a+b)\ (a^2+ab+b^2)=a^3+2a_2b+2ab\ +b^3$.
7. $(a-b)^3=a^3-3a_2b+3ab^2-b^3$
8. $\frac{x^3-y^3}{x-y}=x^2+xy+y^2$
9. $\frac{x^3+y^3}{x+y}=x^2-xy+y^2$

The attention of persons having copies of the 2nd edition of the book is called to these errors, which will be corrected in copies which may be sold in future.

There has lately been found the original contract used in the erection of St. James Cathedral, Toronto, in the year 1839, together with elevations and floor and gallery plans.

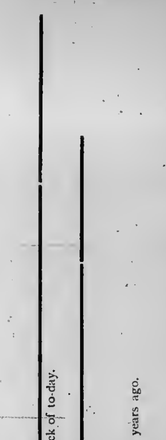
A new Methodist church has just been built at Kingsville, Ont., at a cost of $15,000, from designs by Mr. James Wilson, architect, of Chatham, Ont. The construction work was done by Mr. Thomas Jenner, of Kingsville. The building is said to be one of the best adapted in Western Ontario.

EARLY ENGLISH MOULDINGS.

The exquisite skill, taste and patient labor invariably evinced in the working of early English mouldings are truly admirable, says a foreign exchange. The ingenuity that was never at a loss in any difficulty of finish or constructive irregularity, and the minuteness with which even the most concealed and darkened parts were executed, are circumstances of much interest, and show a love for the art above the sordid considerations of minimum cost. The deepest hollows are all as cleanly and perfectly cut as the most prominent and conspicuous details; and in the village church as much so as in the most glorious cathedral. An early English doorway is often a wonderful piece of art, however little it may attract the attention of ordinary observers. It is most pleasing to notice the long train of dog-tooth lurking in the dark furrow of a label or channeled recess; to see the end of some inconvenient member got rid of by throwing a flower across the point where it suddenly stops or dies into the wall; to admire the floriated boss and the foliaged capital intruding their luxuriance upon the mouldings and hollows, as if they had overgrown their original and proper limits. How beautifully, too, the knots of pierced and hanging leaves extend like some petrified garland or bower of filigree-work round the arch, dividing the plainer moldings into groups, and almost imparting life and vegetation to the very stones. There is an abundance of doorways of this style which exhibit the most delightful varieties in their forms and groupings; always, yet never, the same. Some examples occur at Bolton and Furness abbeys, whose arch moldings extend five or six feet in width. The west fronts of several of our cathedrals have Early English doorways of amazing magnificence. The entrance doorway of the chapter house at Lichfield is a very fine example of the moulding of this style. But almost every cathedral and every ruined abbey will supply good specimens.

THE STRENGTH OF BRICK.

Here is a graphic illustration of the statement made by Mr. Williams in his paper on Vitrified Brick, read before the 7th Annual Convention of the National Brick Manufacturer's Association of the United Stores Touching on the progress of brickmaking in the United States, he quotes from Trautwine, the statement that a column of brick six hundred feet high would crush itself. He takes a test of the crushing strength of annealed brick, and shows that a column ten thousand feet high is required to crush itself; while a column of granite of similar dimensions would crush itself at a height of eighty-one hundred feet. Verily this is a striking illustration of the superiority of the machine made brick of to-day over those made in former years, and is proof that the craft is progressing. What industrial art can show an equal advance in the quality of manufactured products? This illustration of the relative height that a column of certain dimensions may be built of the materials named will give a better idea of the superiority of vitrified or annealed brick than is generally prevalent, even among those who are informed on the subject.



LEGAL DECISIONS.

In the case of Sieyes versus Cure Sentenne *et al*, recently decided at Montreal, plaintiff was leased the premises now occupied by the Compagnie Generale des Bazars, but he was not allowed to enter on the date fixed. He sued and was awarded $1497.84 as damages. Cure Sentenne then sued the contractors in warranty and they were condemned to pay this amount, together with the sum of $525 costs.

DAMAGE FROM DROPPING OF MORTAR.—Where a person sustains damage by the dropping of mortar and bricks during the erection of a wall next to the premises occupied by her, the party for whom the wall was being erected is not liable for such damage, but the contractor would be, if any one, if it was not a necessary result of the building of the wall, but was caused by the negligence of the contractor or of his servants. The injury caused by dust arising from the dumping of loads of brick near a person's residence might be so trifling as not to be actionable, or there might be evidence of such excessive and long-continued annoyance therefrom as to warrant the submission of the question of damage caused thereby to the jury. Pye v. Faxon, Supreme Judicial Court of Massachusetts, 31 N. E. Rep., 640.

PAGE V. DEFOE; BROWN V. DEFOE; ASHDOWN V. DEFOE.—Judgment on motion by the defendant in all three cases, which were tried together before MacMahon, J., and a jury, at Toronto, to set aside the judgment for the plaintiffs and to enter judgment for the defendant; or for a new trial of the action. The defendant was the owner of a storage warehouse in the city of Toronto which collapsed and destroyed the plaintiffs' goods therein stored. The defendant contended that the collapse was not due to any negligence on his part, but, as the evidence showed, to the dry rot in a portion of the timber, for which he was not responsible, having exercised due care in converting the building from its former use as a billiard table factory and in the selection of the material for that purpose. The court held that the collapse was duets dry rot unknown to the defendant, and that there was no negligence on his part. Motinn granted and actions dismissed with costs. Leave given to carry all the cases to the Court of Appeal together, if one of them is appealed, and if the amount in question in any is too small for an appeal, leave granted to appeal.

SMITH V. FORT-WILLIAM SCHOOL BOARD.—Judgment in Chancery Court, Toronto, in action tried at Port Arthur. Action by a resident freeholder, ratepayer and elector, and a supporter ot the Public Schools in the town of Fort William, on behalf of himself and all other ratepayers of Fort William except the ratepayers, against the Public School Board of the town, certain individual members of the board, and Robertson & Ross, contractors, for an injunction to restrain the defendants from proceeding with the erection of a school building in the town, and to compel the repayment to the school corporation of certain sums of money paid by the individual members of the board to the contractors for the work. The learned judge holds that the school board of a city, town, or incorporated village have no power to enter into any contract for the building of a school house until the necessary funds have been provided under section 116 of the Act of 1891, and that if a certain sum has been provided under that section for the purpose of building a school-house they cannot be allowed to enter into any contract or undertake any work involving the expenditure of any greater sum, and theretore that the contract into which the School Board in this case entered was beyond their powers, and not binding upon them. Injunction made perpetual as prayed. If the work done is of some value to the board as the foundation of a smaller building or otherwise, they are to make an allowance for it, to be ascertained by the local judge at Port Arthur. The defendants other than the School Board to pay back to the School Board the whole of the $2,625 paid on account of the contract, with interest from the time of payment, less such sum, if any as the referee shall find for the allowance as above. The defendants other than the School Board to pay the plaintiff's costs of the action.

ENGLISH AND ITALIAN BRICKWORK.

Early English brickwork is now rare. Little Wenham Hall, Suffolk, of the latter part of the 13th century, shows, says the *Clay Record*, different sizes of brick; these are mixed with stone and flint in parts. The brick are of Flemish shape, though some resemble Roman brick or tiles, and the color varies. We must turn to the Eastern counties for examples of English brickwork. In many of these flint is introduced in the form of panels, and this kind of walling is known as "flush work." Nearly every important church is of this mixture of brick or stone and flint. Layer Marney Hall, Essex, is a noted example of brickwork. The great gatehouse of three stories, flanked by octagonal turrets, with battlements and parapets, and window mullions, exhibits an advanced stage of brickmaking and workmanship. Respecting the size of English bricks, those at Little Wenham Hall measure 9¾ inches in length by 4¾ inches wide and 2¼ inches thick. Those made in Edward II.'s time measure 10 and 12 inches long by 5 and 6 inches wide. The "great brick" of 1374, measured 12 inches long, 6 inches wide, and 3 inches thick. Portions of Hampton Court Palace show some beautiful examples of English brickwork, to which the attention of the student may be directed.

The late Mr. Street, a great authority upon Italian brickwork, points out in his work on "Brick and Marble Architecture" to what a large extent red brick is used with stone. Italian brick are rather larger than ours, but not of better quality; the joints are wide, generally not less than half an inch. The brick used for windows, doorways, and other ornamental features are of finer quality and moulding.

Those who know Italian examples of brick arches and tracery are aware that the cusping of arches is of brick, set in the same radiating lines as the arch, and cut and rubbed to the outline required. He says: "In nearly all cases where brick is used for tracery, it is in the shape of plate tracery. The tympanum of the arch is filled in with a mass of brickwork, through which are pierced the arches over the several lights of the window, and these are supported on marble or stone shafts, with carved capitals instead of monials; and above these sometimes, as in the windows of St. Andrea, Mantua, are three cuspid circles, sometimes only one; or else as in the cathedral of Cremona, the plain brick tampanum is relieved by the introduction of a panel of terra-cotta, bearing the cross on a shield, whilst round its outer circumference delicately treated though large cusping defines the outline of the arch." Outside the arch sometimes a red brick label 2½ inches wide is introduced. In Mantua and Asti these narrow bricks are set between rings of brick and stone voussoirs.

THE "EMPIRE" SCROLL SAW.

This machine is designed for carpenters, builders, cabinet makers and general workshop use; it is thoroughly practical, strong and durable, will cut up to 3 inches thick, and swing 24 inches.

It has wooden arms operating upon an entirely new principle being pivoted in such a manner as to do away with any side-motion, and in connection with the self adjusting saw clamps gives a straight up-and-down motion of the saw blade.

It is arranged to use regularly, 8-inch saw blades, but can be adjusted to use 5-inch blades for very light work, if desired. It has an iron tilting table turned true and polished, which can be changed to any angle for sawing inlaid work. It has an adjustable upright drilling attachment, provided with an "Empire" drill chuck, which will hold from No. 60 to 3-16 inch twist drills. The driving wheel is 24 inches in diameter and the driving belt being the patent V shape, strong power is obtained without any slipping or lost motion.

The foot power has a walking motion, by which much power can be obtained with little fatigue, and it enables the operator to run the machine with both feet, sitting; or one foot, standing, as desired.

The average rate of speed when sawing is about 800 strokes per minute. The height from floor to top of table is 40 inches.

For steam power, tight and loose pulleys, arranged to connect with the driving wheel shaft, are furnished.

The Victor lathe can be used on this machine. Weight of machine, 155 pounds. Boxed for shipment, 240 pounds. This machine is manufactured by the Seneca Falls Mfg. Co., of Seneca Falls, N. Y., from whom any further information may be obtained.

THE "EMPIRE" SCROLL SAW.

CASTING PLATE GLASS.

The casting tables, the most important pieces of apparatus in a plate-glass works, are nineteen feet long, fourteen feet wide and seven inches thick. Each is provided with an iron roller, thirty inches in diameter and fifteen long. Strips of iron on each side of the table afford a bearing for the rollers, and determine the thickness of the plate of glass to be cast. The rough plate is commonly nine-sixteenths of an inch in thickness; after polishing it is reduced to six or seven sixteenths. The casting-tables are mounted on wheels, and run on a track that reaches every furnace and annealing oven in the building. The table having been wheeled as near as possible to the melting-furnace, the pot of molten glass is lifted by means of a crane, and its contents quickly poured on the table. The heavy iron roller is then passed from end to end spreading the glass into a layer of uniform thickness. The whole operation of casting scarcely occupies more time than it takes to describe it Each movement is made with almost nervous rapidity. Few industries offer such fine scenic display as the pouring of molten glass. One feels like crying "encore!" it is so very brilliant. In contact with the cold metal of the table the glass cools rapidly. As soon as possible the door of the annealing-oven is opened, and the plate of glass introduced. The floor of the oven is on the same level as the casting-table so that the transfer can be conveniently and quickly made. When, after several days the glass is taken out of the oven, its surface is found to be decidedly rough and uneven. A small quantity is used in this condition for skylights and other purposes where strength is required without transparency. It is known in the market as rough plate. The greater part of the glass, however, is ground, smoothed and polished before it leaves the establishment.

FIREPROOF CONSTRUCTION.*

In a thoroughly fireproof building it is not alone necessary that the materials of construction should be incombustible and covered with burned clay. (1) The clay used in the manufacture of the fireproofing material must be of a certain kind. (2) The forms of the pieces and the method of putting it together and securing it in place must be based on scientific principles and the experience of those who have studied the subject.

The clay must be of the refractory kind. That is, it must be either a plastic fireclay, a semi-fireclay, or a fireclay mixed with a plastic clay or shale. The best fireclays are too "short" for this purpose and too brittle if highly burned. In the manufacture of porous terra-cotta very few clays have been found that are both practicable for making a good article and reliable to resist fire when in use. So far as I know they have only been found in three places—Brazil, Indiana; Chaska, Minnesota, near Minneapolis, St. Paul; and in some parts of eastern New Jersey. For the manufacture of hard fireclay material, proper clay can be found in many localities. The best I know of are in Utica and Ottawa, Illinois; St. Louis, Missouri; and the eastern clay belt of Ohio, where they exist in the greatest quantities. They are all white and buff clays—the buff clays being preferable on account of their toughness. No clay that burns red or salmon color is fit for a fireproof building material. Of this I am positive. The greatest errors of American architects have been in the acceptance of so-called fireproof materials made of inferior clays.

The form and method of assembling and securing the fire-proof clay materials are the next essential considerations. They involve many principles of construction and provision against expansion, a description of which the limits of this paper will not admit. In securing the material to constructive steel and iron-work many mechanical expedients must be resorted to. The avoidance of these expedients rather than their too extensive use is to be sought. This can be obtained by forms of material that are to a certain extent interlocking, and a special study is often required in new cases constantly arising. I have often seen in specifications the requirements of mechanical expedients or fastenings, with iron straps and bolts where they might best be avoided, and too much of the same in practice. It is too often forgotten that it is useless to employ for fastenings the same material that we are trying to protect. As a general principle where metallic fastenings or hangers are necessary they should always be either concealed within the fireclay or covered with mortar. All suspended fireproofing should be secured from the back or edges. As an illustration, the common form of roofing with T-irons and book tyles is not a fireproof construction, and will sag and fall from slight exposure to fire on the other side, though thoroughly fireproof on the upper surface. It should not be used unless protected by a suspended fireproof ceilnig, all communication with the intervening space being permanently cut off. As a further illustration, all girder covering supported by straps or bands on the outside is useless, and all wooden blocks built into fireproof materials should be avoided.

*From a paper by J. B. Wright, Consulting Architect, Chicago.

The Toronto Steel Clad Bath Co. have issued a supplement to their catalogue in which they call attention to their steel clad bath No. 2, and to the fact that after the 1st of May next they will decorate all steel clad baths in light green enamel, with the standard relieved in gold, without extra charge.

USEFUL HINTS.

The follow ng collection of recipes will be found useful for cleaning various kinds of materials:—

Brass or Copper, to Clean—Mix together 1 oz. oxalic acid, 6 oz. rotten-stone and ½ oz. gum arabic pounded finely. Add 1 oz. sweet oil and sufficient water to form a paste. Apply and rub dry with flannel or wash-leather.

Brass, to Clean.—(1.) Wash with rock alum boiled in strong lye, in the proportion of 1 oz. to a pint; polished with dry tripoli. (2.) Coat the part to be cleaned with a piece of rag moistened with nitric acid; as soon as it turns a light vellow, rub dry.

Bronze, to Clean.—Fly specks, etc., may be removed by means of a mixture of lavender oil, one drachm; alcohol, one ounce; water, one and one-half ounce. Use soft sponge, rubbing as little as possible.

Bronze Statuary, to Clean.—Use weak soapsuds or aqua ammonia.

Brushes, Hair, to Clean.—Dissolve a piece of soda the size of a walnut in a quart of water. After combing out the hair from the brushes, dip them, bristles downward, in and out of this solution, keeping the backs and handles as free from the water as possible. Repeat this until the brushes look clean. Then rinse in cold water, shake well and wipe the backs and handles with a towel, but not the bristles, as it makes them soft as does also the use of soft soap. Set the brushes in the sun or near a gentle fire.

Brushes, Paint, to Clean.—(1.) Clean with turpentine, pressing out all particles of color upon a marble slab, and then suspend in jars of water not allowing them to touch the bottom. Change the water twice a week. (2.) To clean old paint brushes which have become hard with paint, soak the brushes twenty-four hours in raw linseed oil; then rinse in hot turpentine, repeating the process until clean.

Emery, to Clean After Using.—Boil with caustic potash, stirring constantly, then wash with dilute acid, and dry.

Files, to Cleanse.—Rub with a scratch brush moistened with a few drops of benzole.

Floors, to Extract Paraffin Oil from.—Apply a strong, hot solution of oxalic acid, and afterwards use the scrubbing brush.

Glass, to Clean.—For glass that has been run onto with colors while doing the frames; first take a sharp edged putty knife, but one which has no nicks on the edge, cut the paint off as low as you can without scratching the glass. Rub with a mixture of turps, oil and pumice stone. Clean off with a rag and soap. Wash and polish with a cotton rag.

Granite, Removal of Stains from.—(1.) A paste of 1 oz. oxgall, 1 gill of strong solution of caustic soda, 1½ tablespoonfuls of turpentine, with enough pipe clay to make it thick, scour well. (2.) Use strong lye or make a hot solution of 3 lbs. of common washing soda dissolved in 1 gal. of water. Lay it on the granite with a paint brush.

Grease Spots, to Kill before Painting.—Give the surface a wash with saltpeter in solution or very thin line whitewash. Soapsuds if used, must be well rinsed off or the paint will not dry over.

Grease, to Remove from Stone Steps.—Pour strong soda or boiling hot water over the spot; lay on it a little fuller's earth made in a thin paste with boiling water; let it remain over night and if the grease be not removed repeat the process. Grease may sometimes be removed by rubbing with a hard stone, using sand and very hot water with soap and soda.

Hair Pencils, to Clean.—Rinse with turpentine; work the brush in fine ashes, and shake the hair out well.

Hands, to Clean.—To remove paint use linseed oil and if necessary turpentine also. Use a nail brush instead of a knife for cleaning around the nails. Do not brush too often. After the hands are well brushed, washed and *rinsed*, dry on a soft towel and apply the following, pulverized borax three drachms, dissolved in two tablespoonfuls hot water, add to this glycerine, ounce, bay rum one ounce, a few drops perfume. A few drops after cleansing the hands and before going to bed will keep them soft and white, and remove the dry and uncomfortable feeling of which so many painters and paper hangers complain. (2.) Take a wine glass full of eau de cologne and another of lemon juice; then scrape two cakes brown Windsor soap to a powder and mix well in a mould.

Iron and Steel to Clean and Polish.—Saturate a spongy piece of fig tree wood with a mixture of sweet oil, and finely powdered emery and with this well rub all the rusty parts. This both cleans and polishes, rendering the use of whiting unnecessary.

Iron and Steel, Fine, to Clean from Rust.—Cleanse first with a paste made of ten parts tin putty, eight of prepared buck's-horn, and twenty-five of spirit of wine. Then rub with soft blotting paper.

Mahogany, to Remove Spots from.—Apply a little aqua fortis and water or oxalic acid and water, rubbing the part with a cork till the colour is restored, being careful afterward to wash the wood with water, and to dry and polish as usual.

Marble, to Clean.—Mix soda, pumice stone and finely powdered chalk in proportion of two parts of the former to one of the latter; pass through a sieve and mix with water to form a paste of same consistency. Rub well into the marble and rinse with water.

Marble Busts, to Clean.—(1.) Remove dust and wash with very weak solution of hydrochloric acid. Soap injures the color of the marble. (2.) Brush the marble with a clean paint brush dipped in a solution containing

---

Mr. H. E. Burnett, manager of the building firm of Wm. J. Davis & Co., Chicago, has recently visited Canada with the object, it is said, of establishing a branch of the firm's business in this country.

The Carpenters' and Joiners' unions of Montreal are said to have recently made arrangements with most of the contractors of that city whereby in future 9 hours shall constitute a day's work. The unions are also said to have determined a standard day's pay for all carpenters, the enforcement of which will be attempted after the first of May next.

CANADIAN ARCHITECT AND BUILDER.

VOL. VII.—NO. 2. FEBRUARY, 1894 PRICE 20 CENTS $2.00 PER YEAR.

—THE—
CANADIAN ARCHITECT AND BUILDER,
A Monthly Journal of Modern Constructive Methods.
(With a Weekly Intermediate Edition—The CANADIAN CONTRACT RECORD),
PUBLISHED ON THE THIRD THURSDAY IN EACH MONTH IN THE INTEREST OF
ARCHITECTS, CIVIL AND SANITARY ENGINEERS, PLUMBERS, DECORATORS, BUILDERS, CONTRACTORS, AND MANUFACTURERS OF AND DEALERS IN BUILDING MATERIALS AND APPLIANCES.
C. H. MORTIMER, Publisher,
Confederation Life Building, - TORONTO, CANADA.
Telephone 2362.
64 TEMPLE BUILDING, - - MONTREAL.
Bell Telephone 2299.

SUBSCRIPTIONS.
The CANADIAN ARCHITECT AND BUILDER will be mailed to any address in Canada or the United States for $2.00 per year. The price to subscribers in foreign countries, is $2.50. Subscriptions are payable in advance. The paper will be discontinued at expiration of term paid for, if so stipulated by the subscriber; but where no such understanding exists, will be continued until instructions to discontinue are received and all arrearages paid.

ADVERTISEMENTS.
Prices for advertising sent promptly on application. Orders for advertising should reach the office of publication not later than the 15th day of the month, and changes of advertisements not later than the 5th day of the month.

EDITOR'S ANNOUNCEMENTS.
Contributions of technical value to the persons in whose interests this journal is published, are cordially invited. Subscribers are also requested to forward newspaper clippings or written items of interest from their respective localities.

Subscribers who may change their address should give prompt notice of same. In doing so, give both old and new address. Notify the publisher of any irregularity in delivery of paper.

TO ADVERTISERS.

For the benefit of advertisers, a copy of this Journal is mailed each week to persons mentioned in the CONTRACT RECORD'S reports as intending to build, with a request to consult our advertisement pages and write advertisers for material, machinery, etc.

As we go to press the annual convention of the National Association of Builders of the United States is being held at Boston, Mass. The convention will continue for three days. An important feature of the programme is an address by the Hon. Carroll D. Wright, Commissioner for the Department of Labor for the United States, on "The Relations of the Employer and Workman." A discussion will follow the address, with the view of taking action toward the improvement of the Association's form of permanent arbitration.

THIS number of the CANADIAN ARCHITECT AND BUILDER is largely devoted to a report of the proceedings of the annual convention of the Ontario Association of Architects. Notwithstanding that the number of our pages has been increased it has been found necessary to hold over the publication of several interesting papers read at the convention. In point of interest the meeting was unquestionably one of the best in the history of the Association. The proposal to form a collection of photographs at the School of Science of the work of Canadian architects, and submit the work represented by the photographs to the criticism of the members of the Association, should serve to awaken interest in the Association and increase the attendance at future conventions.

WE wish to call the attention of our readers, especially the students, to the new "Students' Department," which will be found henceforth in every issue of this journal. It is our intention to devote this space to the use and advantage of students, although the "Intercommunication Column" will be open to all readers. This column with the questions and answers given this month, speaks for itself, and we invite the co-operation of all able to supply the required information, to make this a valuable department. Questions will be published in the next issue after they are received, and all answers received in the following issue, but when a question is received requiring *an immediate* answer, we will endeavor to supply it in the first issue. We invite additional answers to those given this month. This department will contain a large amount of information, which it will be well for students to keep on file. In this department this month will be found particulars of another competition for students. To students in the employ of architects who are subscribers to the CANADIAN ARCHITECT AND BUILDER, the MONTHLY EDITION of this journal will be delivered postage free for ONE DOLLAR per year. The order for subscription must be accompanied by one dollar and the certificate of the architect in whose office the student is employed. This offer is made with the object of enabling every student to have in his own possession, and accessible when required, the information supplied through this and other departments, and that none may be debarred from entering our students' competitions.

AS will be seen in the report of the proceedings of the Ontario Association of Architects, the CANADIAN ARCHITECT AND BUILDER comes in for some rather rough handling for an editorial note in the issue of November, 1893, which was read in the Convention and which will be found reprinted in the report of proceedings where read. The burden of the strictures upon the comment in question was that it was not proper criticism. Why it should be so classed is hard to say. There was nothing underhanded in the statement, nor was it unbacked by argument, although from the nature of the passage in which the question was treated—a brief editorial note—it was necessary that the argument should be terse and suggestive rather than explanatory. The President of the Association was quite right in repudiating the note as an Association utterance, and might very properly have gone farther and ruled the introduction and discussion of the subject out of order at the outset, for the CANADIAN ARCHITECT AND BUILDER is not published by the

Association, but we think he cannot have caught the meaning of the article when he denounced it as unfair criticism because, as he said, it condemned the Canadian Building at the World's Fair, without stating the reasons for such condemnation, and questioned (as he said) the capability of a Government architect to design work before he has had an opportunity of showing what he can do. As to the first point, it is only necessary to say that the article was not about the World's Fair Building, but about a proposed Governor General's mansion, and the doubtful capability of the Public Works Department to deal with a problem of that kind. That the Canadian Building at the World's Fair is an acknowledged failure was pointed to as a case in point to illustrate the inelasticity of the Department. But it was not the intention of the CANADIAN ARCHITECT AND BUILDER to rest the argument on this example; indeed we were somewhat surprised to find the Association speaking of the building as if the ability of the Department to design were to be tested by this result. In doing so they were—though we may be sure they had not that intention—making a reflection upon the Department more severe than the CANADIAN ARCHITECT AND BUILDER had implied in its note. We had not at all intended to convey the idea that the chief architect's own ability to design was represented by this building. In speaking of the "departmental designer" of the World's Fair pavilion we supposed we were alluding to a subordinate to whom had been intrusted the carrying out of the plan, and in his work we saw an indication of the difficulty which would be experienced by the Department in carrying out the innumerable and unfamiliar details of a large and ornate domestic building. Here is the point. It is not new, and it is not untrue. Whether or not the genius of Mr. Fuller would enable him to surmount the difficulties of the situation is properly a question to consider beforehand, and it was eminently the business of the CANADIAN ARCHITECT AND BUILDER, being as the President said, the only architectural paper in Canada, to raise the question upon the first suggestion that there might be a new residence built for the Governor General. Of Mr. Fuller's talent and ability there is fortunately for the country no question. It has been shown not only in the Parliament Buildings at Ottawa —which were, however, designed when he was a private architect —but in the numerous Dominion buildings which have been built under his control all over the country, and of which the new drill shed now being finished in Toronto is a striking and successful example. We may congratulate ourselves upon the certainty that while Mr. Fuller is the Government Architect the public buildings, small and large, which are scattered over the country and do so much to form the public taste and to influence the prevailing manner of building, will have a merit that will make them an influence for good. But, as was said in the editorial note in question, the forte of his office is organization to secure the thorough design and execution of the types of public buildings which are thus constantly multiplied. Each may be a new case but is referable to a type, and so easily and quickly handled by a band of subordinates trained to that end. Domestic work, and particularly an elaborate piece of domestic work such as the Governor General's residence ought to be, would find the tradition and organization of the office unprepared for it, and we think it is most likely not going too far to say that there would be something in the old training to be overcome as well as something new to be added to it, and could the Chief Architect find time to enter into all this personally? A private architect on the other hand—one carefully chosen by competition, of course—would be more able to give his undivided personal attention to the work; and what assistance he employed would be accustomed to dealing with problems similar in kind. That is the case as stated by the CANADIAN ARCHITECT AND BUILDER. Whether the view taken is right or not may be open to question, but not its fairness nor our right to take it. The article was perhaps too epigrammatic, and so has appeared to have more edge to it than it really had, and has given offence which we regret, but we cannot help fancying that the chief architect himself would be the first to admit that if under the conditions in which a public architect does his work, he succeeds in doing domestic work better than that of the best private architect that can be selected, it will be a great triumph.

MR. EDMUND BURKE,
President Ontario Association of Architects.

MR. EDMUND BURKE.

WE present herewith a portrait of Mr. Edmund Burke, the newly-elected President of the Ontario Association of Architects. Mr. Burke is well qualified to fill this important office with credit to himself and the Association. As a member of the Council for several years, he manifested the deepest interest in the welfare of the Association and performed such valuable service in its behalf as entitle him to the honor which has now been conferred upon him.

Mr. Burke, who is now in middle life, is a native of the Emerald Isle, but has spent the greater part of his life in Toronto, receiving his education at the public schools and Upper Canada College, in that city. On leaving college he entered upon the study of architecture in the office of Messrs. Gundry & Langley, and subsequently, upon the death of Mr. Gundry, formed a partnership with Mr. Langley, which continued until August, 1892, when he assumed the business of the late W. G. Storm. Among the notable buildings with the designing of which his name stands identified, are: McMaster University, Jarvis Street Baptist Church, Trinity Methodist Church, Walmer Road Baptist Church, the warehouse of Messrs. John Macdonald & Co., Union Loan and Building and Loan office buildings, and the residence of Messrs. Robt. Simpson, Henry Darling and D. E. Thomson.

ONTARIO ASSOCIATION OF ARCHITECTS.

The annual examinations of the Association will be held at the School of Practical Science, Toronto, on Tuesday, March 6th, and will continue until Saturday, March 10th.

There will be a public Association lecture at the School of Practical Science on the evening of Thursday, March 8th, beginning at 8.30. The lecturer will be Mr. Grant Helliwell and the subject "Architectural Styles in Use To-day." The lecture will be illustrated by means of the electric light magic lantern of the School of Practical Science, under the management of Mr. Wright. The public are invited to be present.

HAMILTON.

(Correspondence of the CANADIAN ARCHITECT AND BUILDER.)

The inaugural meeting of the Arts and Crafts Association of Hamilton, Ont., was held in the Art School on the 17th ultimo. About 50 active working members were present. Mr. S. John Ireland, principal of the Hamilton Art School, was elected president. The three vice-presidents are each chairman of sub sections: Mr. Stark Jordan, "Fine Arts;" Mr. John S. Gordon, "Craftsmen;" Mr. W. A. Edwards, "Architecure," Miss Baine, Sec.-Treas., with others form a Council. A strong Probation Committee is appointed, who will decide what to admit or reject from entering the exhibitions; they will also superintend the arrangement of exhibits.

The aims and objects of the society are:—

(*a*) To facilitate the exhibiting of fine art work, architecture and handicraft, done by members of the Association, who shall be residents in or natives of Hamilton or its immediate vicinity, and thereby cultivate the public taste for fine art and the products of the crafts which depend on some display of artistic skill to become saleable.

(*b*) To bring selections of the best works of artists, architects and craftsmen, prominently before the public notice so that some of such works at least may find purchasers, which, if left to individual enterprise, would remain unsold.

(*c*) To bring the works of young artists and craftsmen before the notice of those requiring skilled labor.

(*d*) To encourage individual effort among art workers to produce better work, by associating the name of every worker with his or her work, particularly with factory-produced articles which bear the direct impress of the individual thought, skill, or taste of one or more workers, as well as the name of the firm producing such articles.

(*e*) To admit work of other artists, not resident in Hamilton, as long as there is space for the same without overcrowding local work; this is intended to prevent, somewhat, the members of the Association from becoming narrow minded or purely local in their ideas. No distinction will be made between so-called professionals and amateurs.

(*f*) To purchase works of art with any profits derived from exhibitions, after all expenses incurred in holding such are paid, the work so purchased to form a nucleus of a collection for a public art gallery, such purchases to be located temporarily by the council of this association.

(*g*) To hold exhibitions of Hamilton work in other places in Ontario, where such exhibitions are deemed advisable by at least two-thirds of the members of the association.

(*h*) To further cultivate artistic taste, patrons will be enrolled as well as working members by paying $5 per annum or $25 for a life patronage, the money so obtained to be expended in the purchase of works of art to form the nucleus of an art gallery. The first exhibition will be held early in May next.

The partnership existing between Messrs. W. B. Malcolm, of Toronto, and E. Bowler, of St. Johns, Que., under the name of the Dominion Sanitary Pottery Co., has been renewed.

STUDENTS' DEPARTMENT.

NOTICE TO STUDENTS.

TO students in the employ of architects who are subscribers to the CANADIAN ARCHITECT AND BUILDER the MONTHLY EDITION of this journal will be delivered postage free for ONE DLOAR per year. This offer does not apply to draughtsmen whose term of studentship has expired.

The order for subscription must be accompanied by one dollar and the certificate of the architect in whose office the student is employed. This offer is made with the object of enabling every student to have in his own possession and accessible when required the information supplied through this and other Departments, and to enter our competitions.

"CANADIAN ARCHITECT AND BUILDER" COMPETITION.

The publisher of the CANADIAN ARCHITECT AND BUILDER invites competitive designs for a Drug Store, situated at the corner of a street, to cost not more than $3,000. *In this competition a new departure will be made in awarding the premiums.* A selection will be made of six or eight designs, which will be published together and all students employed in the offices of architects in Canada will be invited to vote on them, filling up a form for this purpose which will be supplied in our advertisement pages. Every vote must be accompanied by a short written reason for the choice made, and each voter must give the name of his employer. The design receiving the highest number of votes, with good and practical reasons, will be awarded the first premium, and so on.

This competition is restricted to students who are at present subscribers to the CANADIAN ARCHITECT AND BUILDER, or who shall become subscribers previous to the close of this competition, in accordance with the notice printed above regarding special subscription price to students.

The store is to be placed at the sunny corner of the street, built on the street lines and having a frontage of 22 feet. The Drug Store *itself* is to be 25 feet deep. Over the store is to be provided a residence of two stories and attic for the druggist.

Drawings are required of a front elevation to ¼" scale and a plan of the store to a reduced scale, drawn below the elevation. Each competitor must give a short, concise description of his design, and he is left free to include any conveniences of arrangement that may suggest themselves as suitable for the purpose of the building. The first considerations should be convenience and architectural effect.

The first premium will be $15.00, and the second $5, the third, one year's subscription to the CANADIAN ARCHITECT AND BUILDER.

Drawings must be made on sheets of heavy white paper or bristol board 7x14 inches in size (the seven inches being the bottom of the sheet), and must be sufficiently coarse to allow of their being reduced to *one-half* the above size. Drawings must be made in *firm strong lines* with *pen* and *black ink. No color or brush work will be allowed.* Each drawing must be marked with the *nom de plume* of its author, and the author's name and full address enclosed in a sealed envelope bearing the *nom de plume* outside, must be sent in with the drawing.

Drawings must reach the office of the CANADIAN ARCHITECT AND BUILDER, 107 Confederation Life Building, Toronto, not later than the 7th day of March, 1894.

All designs will be returned to the authors within a reasonable time after the competition is decided.

Students entering this competition must be careful to comply with all of the above conditions.

All practising architects are debarred from this competition.

TORONTO ARCHITECTURAL CLUB.

WE have received through Mr. Fred. P Kelley, who was the Secretary of the Toronto Architectural Club, a letter from the T-square Club of Philadelphia, which is endeavoring to form a permanent organization for the purpose of holding annually or as often as possible, exhibitions of the work of the various architectural sketch clubs in America.

Accompanying the letter is a copy of a suggested constitution for the proposed organization, the government of which is to be vested in a Board of Representatives composed of one member from each club in good standing. An executive committee selected by the Board, is to have full power to direct the entire work, interests, and all legislation governing the exhibitions, not provided for by the constitution. Any architectural sketch club to be eligible to membership on payment of $10.00, and membership to be maintained by payment of a pro rata tax of 25 cents on its membership. The drawings for the exhibitions to include those receiving special mention at the individual club competitions, and can be exhibited but once. The drawings to be judged by a jury consisting of an architect, artist and sculptor, who are to be non-members, and one gold and one silver medal to be awarded to the clubs whose work shall be adjudged to be the best and second best respectively. The writer of the letter requests the co-operation of the Toronto Club for the carrying out of the scheme.

In fowarding to us the letter Mr. Kelley suggests that we should bring it before the eyes of those interested, in the hope of reviving interest in Architectural Club matters in Toronto, in view of the fact that not a few of the former members of the Club who were away in the United States and England, have returned, and the possibility that they might be induced to renew their interest in the Club, and assist in its re-organization. We very gladly give the matter publicity, in the hope that this result may follow.

INTERCOMMUNICATION COLUMN.

This column is intended to afford a means of correspondence for students, builders, and all our readers desiring information they cannot otherwise obtain. Questions for which an immediate reply is required should be marked "Urgent." Names and addresses of correspondents must be sent with their communications, but these may be signed with initials or otherwise for publication.

QUESTIONS.

[1.] Will some reader kindly tell me in what book I can find good examples of Elizabethan details? A. C. B.

[2.] Opinions seem to vary as to the advisability of constructing hollow walls for houses. I should be glad of any authentic information on the subject? Yours, H. W.

[3.] I am very glad to hear of the proposed Intercommunication Column. It will prove an immense boon to many of us. I have a question to ask which will be of interest to a number of students. I want an unbiassed opinion about going up for the O. A. A. examinations. I do not want to go up for them unless it is absolutely necessary to pass them before I can set up for myself in the province. Kindly let me have an answer at once, as I believe the next examinations are coming off soon. STUDENT X.

[4.] As I understand your Intercommunication Column is open to builders as well as all your other readers, I should like to ask a question. The architect of a building just finished has given me a final certificate for my work on it. The owner says he intends to hold the certificate for six months at least to ascertain the soundness of the work. The contract does not state definitely anything about the time for final payment. I want the money, and don't see why I should wait, as the architect has passed it. Has the owner any right to keep me waiting? BUILDER.

[5.] I am serving under a written agreement with an architect, which is supposed to bind me to him for three years, during which time I get no pay. We had a good deal of work for the first year but have had none for the last three months, and I have nothing to do but kick my heels. As the prospect for the spring does not look promising I have asked him to let me go, that I may go somewhere where I shall see more work, for I am anxious to learn, but he says he will not free me at present. If necessary can I get free by invoking the aid of the law?—QUEBECER.

[6.] I should like to get the opinion of fellow students in country places as to forming a club, of say a dozen members, who would unite for the purpose of subscribing to about four leading architectural papers to be circulated among them. I would make the following suggestions: A dozen of us might pay enough for four papers. Someone would act as secretary and buy the papers and start them out to four members. Each member keep each paper three days and send it on; the last man to return it to the secretary, who would be allowed to keep the papers as payment for his services, or they might be sold and the price realized go towards reducing the expenses for the next year.—G.

[7.] Can any one tell me of a way to mount tracings on drawing paper, so that they can be rolled up without injury?—JACK.

[8.] What is the simplest way of telling good cement from bad? In the country we are very much in the power of the builders in this respect, and I have sometimes been badly treated.—ARCHITECT.

REPLIES.

[3.] STUDENT X.—The probability is that by the time you want to set up for yourself the present O. A. A. Act will have been so amended that it will be necessary for you to pass the examinations and you would very much regret, then, not having passed. Under any circumstances you would never regret having been examined. An examination is an excellent goal towards which studies may be directed, and it enables a student to ascertain how much he really knows. We would strongly advise you not to lose the opportunity that is now presented.—ED. "INT. COL."

[2.] In reply to "H. W." I have made it a practice, whenever the expenses would admit of hollow walls, to use them, and though I have often heard objections made to their use, I have never found any disadvantage arise from their use in my work. —N. G. M.

[6.] The suggestion by "G" is a good one, and we would commend it to his fellow students. We shall be glad to help in the formation of such a "Club" if we hear from others about it. —ED. "INT. COL."

ONTARIO ASSOCIATION OF ARCHITECTS.

THE fifth annual convention of the Ontario Association of Architects was held at the School of Practical Science, Queen's Park, Toronto, on Tuesday and Wednesday, January the 16th and 17th. The first session was called for 2 p.m. on Tuesday afternoon, and shortly after that hour the following members had assembled:

David G. Baxter, Stratford; G. R. Harper, Toronto; H. B. Gordon, Toronto; J. W. Power, Kingston; Thomas Kennedy, Barrie; A. E. Paull, Toronto; F. Darling, Toronto; W. A. Edwards, Hamilton; D. B. Dick (President), Toronto; J. Gemmell, Toronto; W. R. Gregg, Toronto; G. W. Gouinlock, Toronto; W. R. Billings, Ottawa; Mark Hall, Toronto; M. B. Aylsworth, Toronto; R. W. Gambier-Bousfield, Toronto; J. W. Gray, Toronto; S. G. Curry, Port Hope; S. G. Kinsey, Port Elgin; E. Burke, Toronto; S. H. Townsend, Toronto; E. B. Jarvis, Toronto; and W. A. Langton (Registrar), Toronto.

The President called the convention to order at 3 o'clock, and the minutes of the last convention were then read and confirmed.

The President then read his address as follows:—

PRESIDENT'S ADDRESS.

We are now assembled in the fourth convention since the incorporation of the Association. This convention marks a critical period in its history, the most critical in fact, which has yet been reached. The past year has been one of great depression in business throughout the world. The United States have passed through a financial crisis of almost unexampled duration if not of unparalleled severity, and the effects of it have been felt in Canada in almost every department of business. This is a kind of reciprocity which no tariff wall, however high, can keep from coming into operation. There has been a universal cry of "hard times." Less money than usual has been available for building purposes. Consequently fewer buildings have been erected, and there has been less work for architects to do. The last similar period of depression occurred after the financial panic of 1873. That flurry was of shorter duration, and its effects on building were not so disastrous, for several reasons. The cost of building was much lower then than it is now. Buildings were fewer in proportion to population, and those who had money to invest exercised a judicious foresight, and took advantage of the low prices to make provision for the needs of the future. The case is different now. Owing to the advance in wages and the increase in the price of materials, the cost of building has increased enormously. But rents have not increased in the same proportion. The cities, too, are more built up in proportion to population. There is therefore not the same inducement offered to those who are in a position to command money, to invest it in buildings. In Toronto these circumstances are aggravated by the fact that she was suffering from a period of severe depression, following naturally on the cessation of the boom which had been going on for some years previously. This is a local matter, but I may be permitted to mention it in consideration of the fact that so large a proportion of the members of the association reside in Toronto. But the depression has been felt in all parts of the country. The decrease in the amount for which building permits have issued in the cities and towns is conclusive evidence of this. And it is probable that the depression has affected, to a greater or less extent, the business of almost every member of the association. In times of prosperity, even a busy man will give more freely, both of his time and means for the advancement of his profession, or any other object that appeals to his public spirit, than he will be likely to do when he is anxious, and perhaps harassed about his own private affairs. It would therefore be too much to expect that this association should not have suffered somewhat from the general depression.

There are also special circumstances connected with the association itself which make this a critical period in its history—circumstances which may have a grave bearing on its future, and which therefore demand our most earnest consideration. I refer especially to the question of the amending of our act of incorporation, and the present position of that question. We did not propose to ask for much—only the elimination of that one little word "Registered." But under the circumstances even that little proved to be too much. Observe, however, that the boon was not refused; because as soon as it became apparent that "discretion was the better part of valour," the bill was withdrawn. One important factor in bringing about this result was the fact that—notwithstanding the accusations that have been freely made against us of an extreme desire to be exclusive—we, unfortunately, got into bad company. We could not, however, help ourselves in this, and were not to blame for it. "Misfortune makes strange bedfellows," and so we found ourselves, however unwillingly on our part, classed with druggists, undertakers, and (save the mark) milkmen—all of whom came asking for special privileges. We need not concern ourselves with the justice or otherwise of the demands of these different bodies. But the result was, as the Premier informed us at an interview with the Cabinet, at which we were most courteously received, that the temper of the House at that time was such, that any proposal which seemed even to point in the direction of increasing the number of close corporations would certainly be voted down. Under these circumstances the only course open to us was to withdraw the bill for the time being. To have persevered and pushed it to a decision would have been to court disaster. Had we done so, and the bill been rejected by, as it is probable, a very large majority, there would have been no hope of its being favourably considered for years to come. Members of the House who had once placed themselves publicly on record as opposed to the granting of our petition, would feel themselves not only free, but bound to oppose it on the next occasion on which it might be brought forward. We should thus have been now in a much less hopeful position than that in which we stand to-day. Practically we are very much in the same position as at the date of the last convention. We have undoubtedly made some friends. So far as I know we have made no enemies, and we have gained a great deal of experience that will be useful in the future. The work that was done last winter has not been thrown away. A good deal of it will not have to be done over again, but rather supplemented by further efforts on the same lines. We have no reason to feel hopeless or even discouraged. When we consider how many similar associations in different countries have failed in their efforts to obtain such legislation as we have been striving after, it seems as if we were perhaps too sanguine in hoping that we should reach our goal at the very first attempt. You are doubtless all aware that the Quebec Association stands in precisely the same position as we do in regard to this question, the work "Registered" having been inserted by the Government in their act in the same way as it was in ours.

A great deal of work was done last winter, not only by the council or the Toronto members of the association, but by many members in different parts of the Province. The work should not be confined to the time when the legislature is in session; it should be going on all the time. Each member of the association should keep it on his mind, and whenever an opportunity offers, he should take advantage of it to set before influential persons in the community, and more especially members present or prospective of the Legislative Assembly, correct views of what our objects and aims are. This can best be done by those who are personally acquainted with the persons whom they wish to influence. Each member should therefore make it his business to persuade the representative of his own district in the House that the granting of our request would be in the public interest. It is only in this way that the desired end can be attained. It is not the members of the Ministry who have to be convinced that our claims are just, but the people and their representatives. This question has been discussed until you are so familiar with the arguments pro and con, that it would only weary you were I to enlarge upon them now. We should not, however, allow ourselves to talk or feel as if this were the sole end and object of our existence as an association. It is only one of our objects. Indeed it is not properly in itself an object at all, but only the means to an end.

It is declared in the original constitution that the objects of the association are "To unite in fellowship the architects of the province of Ontario, to combine their efforts so as to promote the artistic, scientific and practical efficiency of the profession, and to cultivate and encourage the study of kindred arts," as well to obtain legislation. What has the association done to promote these objects? It has certainly done a great deal to accomplish the first named, that of uniting the architects of the province. Before the organization of the association, the architects of the Province were practically unknown to each other. Those who lived in the same place might happen to be acquainted with each other just as other residents might; but if so it was only by chance, and as individuals, not as brother architects. No one could depend upon getting any advice or assistance in a professional difficulty, from any other architect unless he could claim it on the ground of personal friendship, and it is to be feared that professional rivalry was much more frequent than professional friendship. Such a thing as generous emulation was not to be expected. There was no feeling of esprit de corps because there was nothing to call it into existence. There was no rallying point. Each man fought his own battle for his own hand, but not, it is to be hoped, without endeavouring so far as lay in his power to elevate the character of architectural design, and the tone of professional life in his district. But there could not be the same stimulus to exertion in this direction when each man felt himself entirely alone, as there should be now when each can regard himself as one of a large brotherhood, all of whom are striving to advance a common cause and are united in the bond of a common sympathy. A man can carry himself with more confidence when he feels that in any just cause, he has the influence of practically the whole of his profession in the province at his back.

There is something too in the mere feeling of association that compels a man to put forth all his power, and so to do better work than he could do without this stimulating influence. "Iron sharpeneth iron, so a man sharpeneth the countenance of his friend." There is more in this than perhaps may appear at the first glance. Even if it is somewhat indefinable, it is there. If it were not so why should it be a fact that in all ages, men whose aspirations and tastes were similar have sought to associate themselves together in guilds, or companies, or societies? What but this was the origin of Freemasonry, of the old trade guilds, of associations of artists, whether painters, sculptors or musicians? It is by no means solely to advance their material interests that legal and medical practitioners associate themselves together, but also for mutual encouragement and assistance in the advancement of their respective sciences.

An association can make its influence felt in a way that would be impossible for the same number of separate individuals, even if it were possible to get them to combine on occasion for a special purpose. The very machinery for calling them together would be wanting. Take for instance the question of the proper regulation of competitions. The influence of this association has been most distinctly and beneficially felt in regard to this. It is not too much to hope that the Conditions of Competition prepared by this association will soon be the conditions of every competition taking place in the province. All that is required to bring about this result is that the members should be loyal to each other. A gratifying instance of the good which has already been done was the case of the competition for new legislative buildings for British Columbia, when the council of this association was requested by the government of that province to select and send out two experts to assist them in deciding on the respective merits of the different designs submitted, which duty was, I believe, satisfactorily accomplished by our representatives.

It may be necessary on occasion for this association to watch the course of legislation and perhaps to offer active interference; and to do this effectively an association must be so strong as to be able to speak authoritatively on behalf of those whom it professes to represent. It must also be possessed of the sinews of war; and for this reason it is most desirable that the surplus which has been accumulated should not be trenched upon for ordinary purposes to the extent of one dollar more than circumstances render absolutely unavoidable. Again, builders and tradesmen of all sorts are handled together for mutual protection, and where the relations are so intimate as between the builders and the architects, it is impossible but that cases must frequently arise in which negotiation between the two bodies becomes necessary. How are these negotiations to be carried on if the architects are not associated together as well as the builders? The principal reason, however, why we should maintain and seek to strengthen the association is, as it appears to my mind, that it enables us to do something to advance the cause of architectural education. If we cannot do much directly, we can do a great deal indirectly. If we can do nothing more than organize and conduct a complete system of examinations, it be well worth while to have the association even for that purpose alone. If this association is seen to be doing all it can do, that fact will bring to the notice of those who have more in their power, the urgent need for more being done in this direction. After all it is the young who will derive the most benefit from any increase of facilities for architectural education, and it is one of the functions of this association to make such arrangements as will induce or compel the young men to take advantage of them. I venture to say that unless there is a strong association which recognizes as one of the principal reasons for its existence, the duty of promoting the cause of architectural education, no complete or thoroughly comprehensive scheme will ever be formulated by any educational or other body. It is said that a work well begun is half ended. Our most hearty gratitude is therefore due to the legislature of this province, and especially to the Hon. Minister of Education, for that admirable beginning which has been made in this very School of Practical Science in which we are now assembled. Although the number of students taking the architectural course is not so large as we could desire, it is gratifying to see that the number is increasing. There were twelve students during the last session, and seven of these were in the first year, as compared with three in the third; it shows that the number is increasing. There were also a few special students taking partial courses.

It may be said without exaggeration that, with the single exception perhaps of pure literature, there is no calling for which it is so difficult completely to train a student as that of architecture. I mean so to train him that he will be competent immediately to begin practice for himself. The reason is this, that the art of architecture consists in *building beautifully*, not in making even good designs on paper; and no school ever has or will have the

opportunity to erect year by year complete buildings merely to teach students how it is done. It is different with other professions. Take medicine for instance. In that case the student does in the hospital under experienced men, precisely the same work that he will afterwards have to do on his own responsibility. A large part of the students' education must necessarily be obtained in an architect's office, and one of the chief practical difficulties is to combine the school and the office education in such a space of time as students can be got to give to it; which should precede the other is an open question, on both sides of which much may be said. It appears to me that the true solution of the difficulty is to have the two carried on simultaneously, and I do not think that the difficulties in the way of this are insuperable.

The tendency of the age is to do away with a regular apprenticeship, or to make the period of it too short to thoroughly train a youth. How many of the younger mechanics for instance, have served a regular apprenticeship, or have thoroughly learned their trades? Seven years used to be thought not too long a time to serve in learning a trade or business. Has the average youth now-a-days the capacity to learn as much in two or three years as the youth of a former generation could in seven? No! but he is is content with a much more superficial training. Whatever may be the reason for it, I think it is a fact that the sons of our well-to-do people often reach almost to manhood before completing their ordinary school education or beginning the special training for their future business or profession, and that without having taken a university course. The result is that an attempt is made to cram altogether too much into a short time, which is not true education. It neither trains the mind for its future work, nor furnishes it with a permanent store of knowledge. There will be scope enough for the energies of this association in endeavouring to overcome these difficulties, and so to send forth our young men well fitted for their arduous life work.

The principal architectural event of the year has been the World's Fair. It has been an architectural event to a greater degree than any previous international exhibition. The erection of the buildings has excited far more interest in the architectural world than on any former occasion. It was known that a number of the best architects in the country were pitted against each other, not in competition as we are accustomed to see it, but in generous rivalry, under circumstances calculated to make each endeavour to surpass, if possible, his best previous achievements. The plan adopted for securing variety with harmony and a high standard of architectural design, and that in the shortest possible time, was a bold one, and has been amply justified by its success. You all know the story—how a staff of executive officers was appointed with a construction bureau under one chief who was responsible for the construction of all the buildings—how a number of architects were invited to co-operate with them and each other, and with the landscape gradening artists, in designing the different buildings; how they all met together and determined the general ground plan and the main features that were to characterize it: Court of Honour, lagoons, buildings, terraces, bridges, fountains, statuary—how they decided on the architectural style, and adopted a modulus of height for all the principal buildings; how the work was apportioned amongst them, and each went his own way to study out his design; how they met again in conference, each bringing his sketches with him; how the work of each was submitted to the friendly criticism of all until the designs were finally approved of; how they separated again each to work out his design in detail; how, in less than two years from the time when the first spadeful of soil was turned up, some 600 acres of waste and desolate sand marsh were converted into a veritable garden of delight; how the artistic dream of the enthusiastic co-workers became a reality, as the colossal buildings rose by the magic of modern skill and science, and the White City stood on the shores of lake Michigan ready to receive all the nations of the world, and to brave their criticism. It was a magnificent feat, and Chicago has good reason to be proud of it. It speaks volumes, too, for the high sense of public duty, and the self-abnegation of the local artists, that out of the six buildings surrounding the Court of Honour, only one, and that one of the smallest, was reserved for a Chicago architect.

The Centennial Exhibition at Philadelphia, in 1876, has often been spoken of as the beginning of a new era in American art. The Columbian Exhibition of 1893 will be equally far-reaching in its educational influence. It is not too much to say that millions have, for the first time in their lives, been brought face to face with real architecture, and under such favourable circumstances that even the dullest imagination could not fail to be impressed. The eyes of many a visitor must have been opened to the true character of the abortions that do duty for architecture in his own particular locality; and recollections of what was seen at the World's Fair may prevent the perpetration of at least some others like them in the future. An exhibition of views and a discussion on this subject are to form one of the features of this convention. I shall not therefore take up your time by enlarging upon it now.

Another interesting event which has taken place during the year, illustrates the advance which the art of architecture has made on this side of the Atlantic within the last generation. I refer to the presentation by the R. I. B. A. of the Royal gold medal to Mr. R. M. Hunt. This is the first instance in which the medal has been awarded to any but a European. When Fergusson wrote his History of Modern Architecture, that of the United States was hardly considered worthy of notice at all—so little, indeed, that even in that voluminous work, his criticism of the architecture of the whole of North America, from New York to Salt Lake City, occupied only six pages of letter-press. The history was published in 1862, and the following sentences convey a fair idea of the author's opinion of the state of American architecture at that time:—"The perfection of art in an American's eyes would be attained by the invention of a self-acting machine which should produce plans of cities, and designs for Gothic churches or Classic municipal buildings at so much per foot superficial, and so save all further trouble or thought." "Notwithstanding the defects of their system, the Americans have lately shown a great desire to display their wealth in architectural magnificence, and to rival the old world in this respect; and have produced some very showy buildings, but certainly not one which can be seriously commended as an artistic design, and still less any one which can be quoted as a well thought out expression of a mind imbued with architectural taste and knowledge." Were he writing that history now, one would be curious to see what he would have to say about American architecture. There would of course be criticism some of it no doubt severe, but it would be admitted that there was something worthy of criticism. This great change is chiefly due to the efforts of a band of capable and well trained men, of whom Mr. Hunt is one of the foremost, who have for years been stamping their individuality on the architecture of their country. These men are fortunate in that most of them have been in the zenith of their powers at that period in the development of their country when vast opportunities were afforded for the exercise of architectural talent. Several of these men have proved themselves equal to the occasion, and none more conspicuously so than Mr. Hunt. We are all less or more familiar with his works, and perhaps more particularly with that which has brought him most prominently into the eye of the public, the Administration Building at the Chicago exhibition; and there will be no difference of opinion that Mr. Hunt has fairly earned the high honour which has been conferred upon him. It is gratifying to observe from the whole tone of the proceedings at the presentation ceremony, that Mr. Hunt was not regarded as in any sense provincial, but as a man of high artistic attainments who could meet on equal terms the leading architects of the world, and hold his own amongst them.

It is of special interest to us to note that while Mr. Hunt is undoubtedly gifted with the natural faculty for design, he has also had unusually good opportunities for cultivating it, and of these he has taken full advantage. It happens not infrequently, especially in this country, that a young man will enter an architect's office, without having previously made any special study of subjects bearing on the profession, and after spending three or four years in the office, will start in practice on his own account, being enabled to do so through the influence of unwise friends who can put work in his way. In such a case the chances are that he will never do anything worth looking at, or worthy of being perpetuated in enduring materials. Mr. Hunt's training was very different, as the result is also. An American by birth, he received first a good general education, partly in his native country and partly in Europe. He then spent some time in the office of an architect in Geneva, and afterwards went to Paris, where he studied under an eminent architect and entered the Ecole des Beaux Arts, where he studied for some years. After leaving it, he travelled for a time, seeing the best architectural examples of Europe, Asia Minor and Egypt. Returning to Paris, he was employed for a time under his former master in making the drawings and details for the Pavillion de la Bibliotheque of the Louvre. About ten years were thus spent in study and preparatory work, after which he returned to America, where he first spent six months in assisting the late Thomas U. Walter at the Capitol at Washington, after which he went to New York and began practice on his own account. He was by that time about twenty-eight years of age. Unfortunately few young men who have to earn their own living have either the opportunity or the disposition to pursue such a course of training and preparation as Mr. Hunt did. If it were otherwise, a greater number might rise to something like the eminence in their profession which he has attained.

It appears strange, and is certainly lamentable, that when such men as this are to be found in the country, the United States government should not take advantage of their skill and talent in the erection of their public buildings. These are the last to which an American would call the attention of a foreigner as typical examples of the best architecture of the day. This is not because they are cheap, for they are said to cost almost exactly double what the same buildings would cost if erected by private persons. It is also said that the cost for architectural service amounts also to almost exactly double what the fees would amount to if the work were done by private architects. This is startling but not surprising under the system that has hitherto been followed. One supervising architect, employed at a salary utterly inadequate to procure the services of a first-rate man, has been expected, with the assistance of an army of clerks—draughtsmen, tracing clerks, computing clerks, and so on—to design and supervise every year buildings costing many millions of dollars, and to see to the expenditure of millions more in repairs. It is physically impossible that any man could be found equal to such a task. Chiefly through the efforts of the American Institute of Architects, a bill has now been passed, providing that in future the design and construction of important public buildings will be entrusted to capable architects in private practice. The necessity for the change is illustrated by the condition of the Chicago post office, which was erected only a few years ago, but which a competent board of experts has now declared to be so unsafe that it is liable to fall at any moment on the heads of its occupants. It may be mentioned here that the principle which has now been adopted by the United States government has to some extent been put in practice by our own Dominion government. And it would no doubt be followed to a still greater extent if the development of the country were such as to require the erection of public buildings at such a rate as to outstrip the capacity of the Department of Public Works.

Another interesting architectural event during the year was the Congress of Architects in connection with the World's Fair. The advisory board consisted of leading architects from the United States, England, France, Germany, Italy, Spain, Hungary, and even Japan. This was the first world's congress of the kind that ever was held. While the attendance was not, apparently, as large as might have been desired; it cannot but have had a beneficial effect in broadening the views and enlarging the artistic sympathies of those who took part in it; and the sphere of its influence will be vastly increased by the publication of the full report of its proceedings. If it had not been for the existence of architectural societies in all parts of the civilized world, the labor of getting up such a congress, and reaching the representative men amongst all the scattered units of the profession, would have been so enormous, that probably it would never have been attempted.

During last year a committee of the council have considered the advisability of adopting a tariff of fees. You will observe that their report does not enter into the general question of the desirability of having a tariff or not, but merely deals with that of the expediency of adopting one at this particular time. Much may be said on both sides of the question, and it would be well for members to take it into their consideration, and look at it from every point of view so that they may be prepared to deal wisely with it when it comes up at a future time. A tariff is generally desired with the idea that it can be used as a lever to keep the rate of fees up to the scale fixed by the tariff. That is one side. The other is that it can also be used to keep the rate down to the tariff scale. No tariff can provide for every contingency, and cases constantly arise in which the tariff apparently applies, but yet in which the scale of remuneration fixed by it would be utterly inadequate. Many cases may arise in which an architect may fairly consider his services worth more than the tariff rates, cases for instance in which he has made a special study of some particular class of buildings, which does not often occur in the course of ordinary practice, say, by way of example, theatres. It is obvious that the services of an expert would be worth more to one building a theatre than those of an architect who had never designed a theatre before; and yet in the face of a hard and fast tariff it might be difficult for the expert to obtain that higher remuneration to which his greater skill would fairly entitle him. This aspect of the question should at least be taken into consideration. In this connection I commend to your attention the report in the CANADIAN ARCHITECT AND BUILDER for October last of the banquet of the Quebec Association of Architects, on which occasion two of the members of the government were present as guests, and gave entirely opposite advice on this question. The Attorney-General congratulated the association on having no tariff, and strongly advised them never to have one; while his confrere, the Commissioner of Public Works, on the other hand, was equally positive that they ought to have one, and promised the assistance of the government in carrying it through.

There is one other matter to which I should like to refer. During the last session of the Ontario Legislature an act was passed entitled "An act to facilitate the enforcement of the just rights of wage earners and sub-contractors." This act is an amendment to the Mechanics' Lien Act and contains some provisions which it is necessary for architects to bear in mind in case of having to do with a contractor whose solvency or honesty is doubtful. Under the act as it stood previously to this amendment, every one who did any work about a building, including sub-contractors, sub-sub-contractors, mechanics, labourers, and supply men of all sorts, had the right of lien on the building and land on which it stood unless he signed an agreement to the contrary. Under the amendment no such an agreement is valid. The wage earners' claim to the extent of 30 days wages is given

priority over all other claims, and any device adopted by owner or contractor in order to defeat that priority is declared to be null and void. The owner, however, is entitled under the act to retain for 30 days after the completion of the work, or delivery of the materials, an amount equal to 15% of the value when it is less than $1,000, 12½% when from $1,000 to $5,000, and 10% when over $5,000. He is also entitled to pay any just claims for wages or materials, and to charge the amounts to the contractor, provided he can pay the claim without reducing the amount of the drawback below the amount of the above named percentage, but he must notify the contractor of such payment within 3 days. Further, he is entitled to refuse payment to a contractor of any amount exceeding $100 unless the contractor leaves with him an affidavit or statutory declaration that all wages have been paid up to and including the 14th day previously. If the owner makes any payment without getting such an affidavit, he does so at his own risk, and is still liable for unpaid wages. In the event of a contractor failing to complete his contract, the drawback cannot be used to complete the work, so long as any wages are unpaid. Strictly speaking, an architect is not safe under this act in giving a certificate for $100 or upwards at any time without demanding from the contractor such an affidavit as has been described. Practically it would be impossible to carry on business on these terms, because, notwithstanding that it is the law, any respectable contractor would consider himself insulted if asked to bring such an affidavit whenever he came for a certificate. The law throws the responsibility on the owner, but as he may know nothing whatever either about the law in the matter or the financial standing of the contractor, he will naturally look to his architect to protect him in such a case. The moral therefore is, to have if possible nothing to do with doubtful contractors, but if one should happen to get involved with any such, then not to be too delicate to demand the necessary affidavit. If this course were constantly pursued by all architects, their offices would soon be relieved from the unwelcome presence of the shady contractor—the man who from education and habit is incapable of doing good honest work, but whom a short sighted owner will sometimes insist should "get a chance to tender," with the result that a few dollars are saved in the amount of the contract, and hundreds perhaps lost in the quality of the work. It is simply impossible with any amount of supervision to get the same standard of workmanship from a man whose aim is constantly to increase his profits by scamping his work, as from a man who honestly tries to live up to his agreement, or who at least values his reputation and future business connection more than the immediate gain of a few dollars. This is a point which it is difficult to get some owners to recognize, and if this act helps to open the eyes of such to the risks they run in insisting on the employment of doubtful contractors, it will certainly save many an architect from much unnecessary worry and trouble, whether or not it benefits the class in whose interests it has been framed. I may mention incidentally that under this act an architect has also the right of lien, but curiously enough, some of the United States courts have held that he only has that right if he supervises the erection of the building as well as prepares the plans and specifications.

Now, gentlemen, I shall not detain you longer from the business of the Convention, which is the one occasion in each year on which we can meet together to exchange views and opinions, and stimulate each other to do what in us lies to raise the standard of architectural practice in this province. It is a matter for regret that every member of the Association cannot be present with us. I am sure, however, that those who are absent regret this as much as we who are present do. I trust that the fifth year of the Incorporated Association will see us growing in unanimity and strength, and so prove that the labor which has been expended in organizing and building it up will not have been spent in vain.

The conclusion of the address was received with loud and prolonged applause.

The Treasurer, Mr. Edmund Burke, then read his report as follows :—

THE TREASURER IN ACCOUNT WITH THE ONTARIO ASSOCIATION OF ARCHITECTS.

Dr.

1893.			
Jan. 1	To balance from 1892		$2,285 35
"	Cheque from Registrar, collections, fees, prior to February 2nd, 1893		225 25
"	Interest on Registrar's bank deposit		4 02
"	Library fines		1 75
"	Members' fees after February 2nd		346 00
"	Students' registration fees		42 00
"	Students' examination fees		23 00
"	Students' examination papers sold		50
"	Transfer student's articles		1 00

EDMUND BURKE,
Treasurer O. A. A.

We have examined the books, vouchers, etc., of the Association, and certify that the above is a correct statement thereof.

(Signed) HENRY LANGLEY, JOHN GEMMELL. } Auditors.

NOTE—

The income for 1892, excluding bank interest, was	$1,199 10
And the expenditure	1,152 81
The income for 1893, excluding bank interest, was	643 50
And the expenditure	1,083 02

On motion by Mr. Burke, seconded by Mr. Gray, the report of the Treasurer was adopted.

The Registrar and Librarian, Mr. W. A. Langton, then read the following report :—

REPORT OF THE REGISTRAR AND LIBRARIAN AT THE ANNUAL MEETING ON JANUARY 16TH, 1894.

Members.

The following is the state of the roll of membership of the Association :—

Membership on January 1st, 1893—		
Resident members	62	
Non-resident members	71	
Total		133
Registrations during 1893—		
Resident members	3	
Non-resident members	3	
Total	6	
Membership on January 1st, 1894		139
Of these there were—		
In good standing		50
Honorary		1
In arrears for 1893		61
" " " " and 1892		18
" " " " " and 1891		9
		139

Students.

There are 87 students on the list. Of these many have gone away for study or in search of work. Some are I think engaged in other pursuits, but I have received no communication from them renouncing their connection with the Association.

Classified according to the examination required from them the roll of students is subdivided thus :—

For first intermediate examination	13
" second intermediate examination	26
" final examination	48
	87

At the examinations of this year there were 19 candidates, classified as follows :—

First intermediate examination	5
Second intermediate examination	8
Final examination	6
	19
Of these the following members passed :—	
First intermediate examination	2
Second intermediate examination	3
Final examination	2
	7
The following were conditioned :—	
First intermediate	1
Second intermediate	1
Final examination	2
	4

These form came up for examination in September, and all passed but one of the candidates for the final examination. Thus, of the 19 candidates for examination in this year 10 have passed, and of these there are three thus made eligible for registration as members of the Association.

The register for students seeking employment, which was opened at the office of the Registrar in 1892, has been little used by students. Architects on the other hand have often made enquiries about draughtsmen, and some of the students who did give their names to the Registrar have thus procured employment.

Proceedings of the Council.

Besides the meeting on the day after convention for the purpose of electing officers and dealing with matters referred by the convention to the Council, the Council met on May 2nd to consider the report of the examiners, and on June 1st, to consider the report of the legislation committee.

Matters dealt with at these meetings, other than administrative details, were as follows :—

Copies of the Conditions of Competition approved by the convention of 1892 were ordered to be printed, and five copies sent to each member.

The fees for 1893 were fixed, as desired by the convention, according to a a graded schedule based upon the plan defined in the president's address at the convention. This schedule was afterwards reduced as stated below.

The following gentlemen were appointed examiners for 1893, and after the examinations were re appointed for 1894 : Messrs. C. H. C. Wright, S. G. Curry, S. H. Townsend, R. W. Gambier-Bousfield, F. Darling and E. Burke.

As Mr. F. J. Rastrick proposed to retire from the Association upon the completion of his period of service as a member of the Council, it was thought proper to ask him to become an honorary member of the Association.

The principal work of the Council was the endeavor to procure an amendment to the Act of Incorporation such as would make the title Architect the exclusive right of members of the Association in place of the title Registered Architect. The Toronto members of the Council had been appointed by the Council as a committee to procure legislation amending the Act, and were called the Legislation Committee. At the meeting of the Council on Feb. 9th, the following non-resident members were added to the legislation committee : Messrs. Jas. Adams, F. J. Alexander, Jas. Balfour, F. Bartlett, A. Bell, Jos. Connolly, T. Cuthbertson, John Day, J. C. Forster, Fred. Henry, John Kay, Thos. Kennedy, J. W. Kenney, J. Z. Long, J. A. Maycock, A. A. Post, Jos. Powell, Jos. W. Power, F. J. Rastrick, W. Stewart, A. White and J. L. Wilson. By letter and circular the president and local members of the legislation committee communicated with the non-resident members so as to secure concerted action. The committee in Toronto held 13 meetings and were assisted by the solicitor of the Association and the solicitor who had successfully assisted the Provincial Land Surveyors in procuring legislation in the previous year. The bill of amendment was finally withdrawn on May 16th by the advice of its principal supporters in the House. A meeting of the Council was called on June 1st, and the action of the committee in withdrawing the bill was endorsed by the Council.

It was decided at this meeting to keep the cost of the working of the Association as low as possible and to reduce the rate of fees until the time when the question of legislation could be brought up again.

A second schedule of fees was drafted and sent out on June 13th along with the President's circular letter dated June 6th, in which was given an account of the work of the legislation committee and the decision of the Council with regard to fees.

It was intended to introduce, when the Bill amending the Act was in committee, an amendment to the Act providing for the election of the President of the Association by the convention, as desired by the convention of 1893. Failure to accomplish this amendment was involved in the withdrawal of the Bill.

The Library.

The number of loans made from the library during 1893 has been 152, or five less than in 1892. Of the borrowers 41 were architects and 111 students.

All of which is respectfully submitted.

W. A. LANGTON,
Registrar and Librarian.

The Registrar, after reading his report, said that at the last convention instructions had been given the Council to push the question of having customs dues collected properly upon plans coming in from foreign countries. In pursuance of that instruction the Toronto members of the Council had been directed to confer with the Manufacturers' Association (a deputation of which body had been of assistance at Ottawa before on a similar occasion and had promised assistance again), as to organizing another deputation to go to Ottawa. The Council had sought and secured an appointment with that Association, but the proposed meeting was adjourned for the purpose of attending the funeral of the late W. H. Howland. Since then it had not been possible to have another meeting, and the matter was consequently referred to the new Council. Another question was the fixing of a tariff of fees, alluded to by the President, which was brought up in the Council. A committee consisting of the President and Messrs. Townsend and Darling had considered the question and presented a report at the Council meeting that morning, which might be appended to the Registrar's report. The following is the report as read :—

The committee appointed to "consider the advisability of adopting a tariff of fees," beg to report that, having given the subject careful consideration, they are of opinion that at the present time—when the Association has been working for and is looking forward to an important amendment to the Act of Incorporation—it would be inexpedient to do anything that might have a tendency to increase the difficulties in the way of obtaining that amendment. There is no doubt that the principal difficulty in the way of obtaining the desired amendment is the feeling prevailing amongst a large number of members of the Legislative Assembly that the Association is of the nature of a Trades Union, and as the ultimate object of these organizations is almost invariably the increase of the rate of wages, your committee are satisfied that if the Association were at this time to adopt a tariff, it would be misinterpreted as a move in the same direction. If we had once obtained the amendment to the Act for which we are seeking, the question would naturally come up as a logical consequence of the enlarged powers which that amendment would confer, and could then be dealt with effectively without injury to the Association. In the meantime, there is no need for any uncertainty as to what is a fair scale of charges, because the tariffs which have been adopted by almost all associations of architects in this country and in Europe are practically identical, and have again and again been recognized by courts of law as proper and reasonable and as a fair basis on which to settle disputed accounts. Any tariff which we might adopt would undoubtedly be similar in its provisions, as it would be useless to attempt to obtain sanction to a tariff higher than that of all similar bodies, and assuredly the members of this Association would not desire that it should be lower. The scale of charges thus fixed is accessible to all architects and can be as readily appealed to as if formally adopted by the Association. The Architectural Guild of Toronto some time ago prepared and adopted a tariff on the above basis, and copies of it can be procured by any member of the Association on payment of a nominal charge. An excellent plan is for individual members or firms to have the scale of charges printed in some convenient form, as for instance on a corner of their letter paper, where clients could not fail to see it, or elsewhere as they might deem expedient. In conclusion, your committee desire to remind the members that any tariff which the Association may adopt must be sanctioned by the Government, and it will be necessary to show that the proposed tariff is in harmony with the custom and the precedent of our ordinary practice. It is therefore apparent that in the meantime it is of the utmost consequence that all members of the Association should conform their practice to the universally recognized existing tariff.

S. H. TOWNSEND.
FRANK DARLING.
D. B. DICK.

On motion by Mr. Townsend, seconded by Mr. Gouinlock, the report of the Registrar was received and adopted.

DISCUSSION.

Mr. Gambier Bousfield asked if something could not be done by the Association to bring and keep itself more prominently before the public from year to year? Between the annual meetings the public heard nothing of the Association. He would suggest occasional meetings at which papers could be read, and reports of which would appear in the press, and in that way the public would not be allowed to lose sight of the fact that such a body was in existence working for the advantage of the community in general.

Mr. Aylsworth said he could not remember having seen during the year any reference to the Association in the public press, but he had observed a reference to the Architects' Guild of Toronto. That body, he believed, had been asked to select representatives on the Technical School Board. He had no doubt the members of the Guild—of which he was not himself a member—had the interests of the Association at heart, and he thought if a similar case occurred again, it would help the Association if the Guild would turn over to it a matter of that kind, by which means the Association would be brought into prominence and become better known to the public. The Guild had been longer in existence and had a handier name, and he had the impression that in the minds of the public throughout the province it was more prominent than the Association. If such a case should arise during the year it was in the power of the Guild to do something for the Association in that way.

Mr. Gregg thought Mr. Bousfield's suggestion was in line with his own of a year ago, regarding the formation of chapters or branches of the Association. He thought the lack of such a branch in Toronto was apparent, and that such a matter as that regarding the appointment of representatives to the Technical School Board, referred to by Mr. Aylsworth, should go before that branch, as the Association as a whole was probably a better body to appoint those representatives than the Guild.

The President said that so far as he could recollect the matter of the appointment of the representatives on the Technical School Board was the only instance for a number of years in which the Guild had been brought before public notice, and he thought that had been allowed to remain in the Guild's hands to avoid making any change. It had been the policy of the Guild not to interfere with matters that were within the province of the Association. He thought he could safely say that since the Association had been in existence, with the exception of the instance mentioned, no mention had been made in the newspapers of the Guild. In regard to Mr. Gregg's suggestion as to chapters, there would be no difficulty in establishing one in Toronto, but there might be in other parts of the province, and he would like to hear from some of the outside members regarding that.

Mr. Billings (Ottawa,) said that Ottawa was supposed to have an Institute now, but they had never had more than five or six meetings, and he believed the secretary of four or five years ago was still secretary. He could not say whether it had been properly run, but it was not a success. There were not more than one or two other cities outside Toronto that had as many architects as Ottawa, and if it could not be made a success there it could hardly be expected elsewhere. They had had one or two pretty good meetings—one when Mr. Curry came down to explain the working of the Association, but as a general thing there was a great deal of apathy. Even when members did attend they didn't know what they came for. There was nothing to do except to sit down and smoke and read a paper. Even in a large Association like the present, there were but few architects who could find in their experience anything sufficiently novel on which to spend their time and give a paper to the Association. However that might be in Toronto, he felt sure that in Ottawa if meetings were held only when some member had a paper of sufficient novelty and interest to hold the attention of those present, the meetings would not be very numerous.

There was a matter to which, although at present he might be slightly out of order, he desired to draw attention, as it had a bearing upon Ottawa architects. There had appeared in the CANADIAN ARCHITECT AND BUILDER, a paper published in Toronto, the following article :—

"Lord Aberdeen's request for an addition to Rideau Hall has excited comments from the daily press varying according to the political bias of the paper. One paper is for leaving Rideau Hall as it is and forcing our Governor Generals to conform their manner of living to the ideas of our farmers who, the leader writer asserts, are coming to the front in public affairs and will be found on the side of a policy of 'democratic simplicity'. Another paper is for pulling down Rideau Hall and replacing it by a 'respectable looking mansion.' It is, as it has turned out, a pity that this course was not adopted at first, for according to the figures quoted, Rideau Hall, which cost $82,000 to purchase, has cost $553,000 for repairs and alterations. Whether the need of $15,000 worth of more room is sufficient provocation to pull down what has been done and build the respectable looking mansion now, is a question. It would not be an exact response to the request of the Earl, who has not asked for a new mansion bye and bye, but for a few more rooms now. It hardly seems likely that the old Hall with its additions will be pulled down before it has had a life reasonably proportioned to the money which has been spent upon it. When the time does come for it to be replaced it is to be hoped that some steps will be taken to have the work well designed. It is not the class of building that is likely to be well handled by the Public Works Department. The forte of the Chief Architect's office is in its organization for the multiplication of buildings of a similar class. An order for such an unprecedented and (unless the farmer forbids) elaborate piece of work as a new residence for the Governor General would sweep the office like a cyclone. The pavilion representing Canada at the World's Fair has already proved too much for the elasticity of the departmental designer. If a new residence for the Governor-General should get into the hands which produced that work, it is impossible to avoid the conviction that however capacious the mansion might be it would not be 'respectable looking.'"

The portion to which he more particularly called attention was that in which it stated "It is not a class of work that is likely to be well handled by the Public Works Department, etc." Certainly that was not complimentary. He felt sure that no person who sneered in that manner at so distinguished an architect as Mr. Fuller was a member of the Association, or even an architect of this or any other province. The paper in question was supposed to be the organ of the Association, and he did not think the organ of the Association should make statements of that character, and he wished to call attention to the way in

which it was edited. He did not think there was in the mind of any member of the Association any question as to Mr Fuller's ability. In adverting to this matter he desired to say that he was acting entirely upon his own responsibility, and not at the wish or suggestion of any member of the staff reflected upon. He would like to hear the opinions of members of the Association in regard to this question.

Mr. Aylsworth said that after what had been said regarding the establishment of chapters in places outside of Toronto, it was hardly to be expected that it could be done elsewhere. He thought in Toronto the Council might take the place of the suggested chapter and hold meetings whenever occasion offered, which would be noticed in the papers and have the desired effect, while the Guild might still afford the means of social and mutual improvement. It might be a matter of consideration whether some means could not be found by which the Guild would be incorporated with the Association in such a way as to take the place of a local chapter.

The President thought one reason why Mr. Aylsworth's suggestion had not been acted upon was the fact, that the time of the council had hitherto been so fully taken up by the matter of legislation that no time was left for anything else, but he thought the present an opportune time for taking it up, and if possible carrying it into effect. So far as the Guild was concerned, he looked upon that organization as having to a certain extent fulfilled its design, though he would not say it had survived its usefulness. The Association of Architects was largely the outcome of ideas expressed in the Guild. He thought if the Guild was maintained it should be simply as a social organization. The difficulty in regard to the appointment of representatives to the Technical School might be got over by having a meeting of the Council of the Association in Toronto, as it would be a little difficult for the Association as a whole to select those representatives for the Toronto Technical School. In regard to the matter brought up by Mr. Billings, he felt sure all present would regard the publication of such sentiments with regret. It had been said the paper in question was the organ of the Association. There was no other paper which it could make its organ. He would venture to say on behalf of the Association that as an Association they entirely repudiated the publication of the paragraph referred to.

Mr. Gregg said that in order to keep the matter of the formation of branches before the Association he would move that during the coming year the Council consider the advisability of calling occasional meetings of the Toronto members, or of forming a branch in Toronto.

Mr. Burke said that while the wisdom of continuing any discussion of the subject introduced by Mr. Billings might be doubtful, he would point out that all the buildings at the World's Fair on which there was any room for criticism had been very severely criticized. He did not see himself that there was any particular venom in the paragraph referred to; it was written in just the same spirit as the criticism of the other buildings. He did not think it was well to be too thin skinned, for criticism was a good thing sometimes.

Mr. Darling thought Mr. Fuller would not object to any criticism of a work he had executed, but the paragraph referred to was not of that character, but rather an insinuation against his ability to do something for which he had not even had the opportunity of submitting a design.

The President agreed that no one should object to fair criticism, but as had been pointed out by Mr. Darling, the paragraph in question was not a criticism; it did not point out what the defects were, which was the first function of a criticism.

Mr. Bousfield, reverting to the original subject under discussion, suggested the advisability of endeavoring to give a little more publicity to the doings of the Association. The results of the examinations and similar matters might be inserted in the daily press.

Mr. Gouinlock coincided with Mr. Bousfield's views, and thought the meetings of the Council should form the subject of paragraphs in the newspapers.

Mr. Gregg read his motion as follows: "That the Council consider the advisability of calling occasional meetings of the Toronto members for encouraging the formation of a local branch.

Mr. Bousfield seconded the motion.

Mr. Power expressed an apprehension that such a course as was suggested might have a detrimental effect on the Association as a whole.

Mr. Gregg thought the motion was quite harmless; the Council had a majority of outside members, and if they foresaw any danger of hurting outside places the matter would certainly be allowed to drop. He did not think it was going too far to ask the Council to consider the matter, and it put the whole question off for another year.

Mr. Billings thought such occasional meetings as had been suggested might be held by the Association as a whole in Toronto, and any outside members who happened to be here or within reach might avail themselves of them.

Mr. Power described the "Institute of Building Arts" carried on under the auspices of the Illinois Chapter of the Association of Architects in Chicago. They had a large flat which was sustained in this way. The floor space was rented to manufacturers and others having building appliances for sale, who made a display there. This brought in a revenues ufficient to pay the rent of the flat. They had monthly meetings at this room, at which architects from other places could drop in, and a special meeting every three months. He thought a similar arrangement ought to be feasible in Toronto, and would be beneficial to both the architects and those making the display.

Mr. Curry called attention to the difficulty there was even in Toronto in getting members to attend a meeting, pointing to the small attendance at the Convention as an illustration. If the members themselves would not do something to help along it was no use calling upon the Council to call meetings. The Guild which had been spoken of had had very strict rules to prevent this lack of attendance, to which it owed very largely its success. If a reasonable attendance could be depended upon, such meetings as suggested would be all very well, but it was no use attempting it if out of the forty men in Toronto only four or five attended. A man who had spent some hours, perhaps days, in preparing a paper to be read at such a meeting, would think it a very poor return for his labor to have to read it to an empty room. There was too much of a feeling abroad among the members that somebody else should do something to make a success of these meetings. If anything was to be expected it must be through individual action. If it could be shown that there was any desire on the part of members to attend such meetings, as suggested, the resolution was a good thing, if not, nothing could be expected from it.

The President, in order to meet Mr. Power's objection, suggested that the resolution be amended by saying, "Occasional meetings of the members in Toronto," instead of occasional meetings of the Toronto members.

Mr. Gregg expressed his willingness to make the amendment, and the resolution, so amended, was carried.

Mr. Gregg then read the following paper:—

ESTIMATING THE COST OF BUILDINGS FROM CALCULATION OF THEIR CUBICAL CONTENTS.

An architect often finds it necessary to estimate the cost of a proposed building before more than an outline sketch has been prepared and before specifications have been written.

In such a case he naturally brings to mind a building of the same class, which has already been erected, and of which he knows the exact cost. If such a one can be thought of, and if it is of the same general dimensions, he has simply to make allowance for changes that may have taken place in the prices of labor and materials, and has little trouble in arriving at the required estimate. If, however, the Building which seems most suitable for the purpose is somewhat larger or smaller than the one proposed, he finds that by taking its cubical bulk or contents and that of the proposed building as a ratio, he may find the proportionate cost with a great deal of certainty, especially if the difference in size is not great. This experience has led to a system, more or less common, of keeping, for reference, a record of the cost per cubic foot of buildings which have been erected, or upon which tenders have been received, and such a record, although often an imperfect guide, is worth the small amount of trouble required in its preparation, and with the entries made from time to time its value will increase.

Within the past few days I have seen a few of the Toronto architects and they have kindly compared notes with me upon this subject and contributed some information used in this paper, which is written with the object of leading to a further interchange of ideas in the discussion which should follow.

I would recommend the following simple method of keeping a record of cubic contents and cost, and would say that the information an architect has of this kind from his own buildings is the best for him, as it is probable that no other architect is quite similar in his style of work and finish.

A book or a number of sheets of paper should be ruled in suitable widths for the following columns: 1st, date, (year); 2nd, name of building, (or owner); 3rd, where erected; 4th, short description; 5th, cubical contents in feet; 6th, cost of building; 7th, cost per cubic foot; 8th, remarks. The kinds of buildings should be classified so that prices of one class may be seen and compared at a glance in one column. Examples were here shown similar to the following:

Date	Name.	Where Built.	Description.	Cubic Feet	Cost $ c.	Cts. per c. ft.	Remarks.
			13 18.				

In computing the cubical contents the rule most commonly used is to measure the building as a whole or in parts from the bottom of the footings to a point half way up the slope of roof, this being done in parts where there are different heights of roofs, towers, etc. In measuring brick or stone buildings, light wooden porticos or verandas are usually omitted. There should be a uniform system of omitting or including such items as heating, mantels, grates and tiles, electric wiring, or of using two rates, one omitting and the other including these.

Supposing that cubing our public schools would give nearly uniform results, I saw Mr. C. H. Bishop, the Superintendent of Toronto School Buildings, and he kindly made out a list of the cost of twelve buildings recently erected with the rate per cubic foot, and this varied by half and quarter cents all the way from 5 to 7½ cents, the variation not being governed by the number of class rooms. This shows that the system is not perfect, and that for very correct results, other methods must be used.

I shall close with a list of the most common classes of buildings, giving a price for each per cubic foot, simply as an opinion which may be altered upon further observation. It is intended for Toronto, and is probably higher than in other places in Ontario.

Plain stables, brick, not including complete iron fittings	7c.
Plain brick dwellings, detached or semi-detached, pine finish, furnaces and mantels	8c.
Detached brick dwellings with plain stone trimmings, hardwood finish on ground floor, hot water heating and mantels	10c.
Detached dwellings, brick or stone, with more elaborate cut stone work, hardwood finish throughout, best plumbing fixtures, hot water or steam heating, elaborate mantels, electric wiring, etc.	15c.
School houses, brick, including furnace heating	6½c.
Churches, plain brick, furnaces and pews included	7½c.
Churches, stone, steam heated, including pews and electric wiring	9½c.
Shops, with dwellings over, plain brick	7c.
Foundries or warehouses with earth floor, one story	3c.
Plain one story warehouse, floored	4c.
Wholesale warehouses, five or six story, brick fronts, with cut stone dressings, heated, office only finished	6½c.
Plain brick office buildings, heated	9½c.
Bank buildings, brick, with cut stone dressing, 2 fronts (on corner)	20c.
Hospitals, brick, steam heating included	8½c.

Mr. Burke said he was unable to agree with Mr. Gregg's opinion that cubing is not much use and is rather inclined to be incorrect. He thought in practice it was found to be just as correct as the builder's estimate, and that the very difference in the cubing of schools showed it. Probably the reason for the great margin in the different schools was to be found in the builder's estimates, not in the principle of cubing.

Mr. Gregg said he looked at the question as it came before an architect in connection with preliminary sketches. The architect is given an order for a building and wants to give an estimate of the cost. How was the architect to know that in that particular case the builders would go away down below the value?

Mr. Jarvis thought from his experience that Mr. Gregg was pretty nearly right.

Mr. Bousfield thought another column might with advantage be added to what was already given by Mr. Gregg. That was the cost per head for schools or churches. Hospitals, too, were very often tabulated at so much per bed. All these were important helps for getting at the actual cost of a building, because, as Mr. Gregg had said, every building varies considerably. Hospitals must of necessity vary according to their character, whether for general purposes, for children, or for infectious diseases. All were regulated according to certain hygienic rules, some requiring more air space than others, and so on. The information that hospitals cost so much per cubic foot gave very little guide to anyone else unless it was known what class of hospital it was, and the cost per bed as well as per cubic foot. Then, with regard to bow windows, cupolas and that sort of thing, they were very easily overlooked in estimating by the cubic foot. In carrying out a design such things were frequently added, and they knocked all calculations by the cubic foot on the head, because they are in themselves expensive additions. His experience had been that everything of that kind had to be very carefully calculated.

Mr. Gregg quite agreed with Mr. Bousfield; he thought every oriel window, tower, etc., should be taken. He thought the ideal way of finding the cubic contents was to find out exactly what amount of space taken out of the atmosphere was filled by the building. He had heard a story of the origin of the word Eureka to the following effect: A man who had been seeking to find the cubical contents of his body was taking a bath one day, and noticed that when he entered the bath the water rose to a certain height. It struck him then that if he measured the size of the bath between the point the water had been at before he got in and the point to which it rose he would be able to arrive at the cubical contents of his own body, and he was so delighted at his discovery that he jumped out of the bath and ran naked through the streets, shouting, "Eureka." (Laughter). If that plan could be adopted with a building it would give it with exactitude; it had to be done somewhat roughly, but the nearer you could get to exactitude the better.

Mr. Townsend disagreed with Mr. Gregg on the same point taken by Mr. Burke. He thought the cubic contents based upon a building of the same sort was far more likely to be right than a builder's estimate. In a case in court not long ago the Judge had taken his cubic contents in preference to the builder's estimate. He thought Mr. Gregg's suggestion that architects should confer together on this point a very valuable one, for if they could agree upon some uniform method in their calculations of cubical contents it would be very helpful.

Mr. Jarvis said the class of work an architect did varied so much that the accurate way to find out what your own work would cost was to refer back. Some architects could get work done cheaper than others, who were regarded by builders as pernicketty, and that for that reason charged 30 per cent. more when working under them. Each man therefore was the best judge, as to the cubical contents, of the cost.

Mr. Gregg said that was exactly what he had found in comparing notes with a few architects, and it seemed to him that it would be quite impossible to make a table of the cost of buildings in Toronto based on the prices given by a number of architects, and that was why he had closed his paper in the way it did. His object in giving the prices was not as a guide, but merely as a beginning or essay for each class mentioned.

Mr. Gouinlock supposed the prices given by Mr. Gregg would be altered according to the varying prices of the building trades.

Mr. Gregg said his figures were principally based upon the prices of the last three or four years.

Mr. Gouinlock said he had made a calculation of one or two buildings, and he found only a cent per cubic foot on factory buildings and half a cent per cubic foot on residences of difference between Mr. Gregg's figures and the cost of work actually done this year.

Mr. Aylsworth interpreted Mr. Gregg's tables to be more as a suggestion that each architect might utilize in his own way, and as such he thought it very useful, but he did not think it was adapted to be used as a hard and fast rule. It might, as had been suggested, be used in law courts, but he thought that would depend to a very large extent on the amount of confidence the presiding judge had in the architect's ability. He did not understand it was intended as a rule for all to adopt, but each architect in his own practice could make it very useful and valuable.

The President said he thought the members were very much indebted to Mr. Gregg for his paper. There was no question about the value of the method of arriving at an approximation by cubing. He did not think, however, that Mr. Gregg intended the figures he had given to be sent forth for the guidance of architects as an infallible rule. He supposed most of those present used the cubing system more or less, and he thought it was really valuable if used with proper discretion, but it ought to be used with a great deal of care, because it was very easy to get different results from different systems. Each man must work out his own system, and by keeping a record of the cost of his own buildings he would be enabled to get better results. A point to be borne in mind was that the comparative size of a building made a great difference in regard to the cost, especially in the case of buildings which may be divided into large or small rooms, schools for example. There would be a great difference between a school divided into rooms holding say twenty pupils and one divided into rooms holding fifty. The same would apply to dwellings. He thought the members were very much indebted to Mr. Gregg for his valuable contribution. (Hear, Hear.)

The convention adjourned at 5 o'clock p. m., until 10 o'clock on Wednesday morning.

SECOND DAY.

The proceedings of the convention were resumed at 10:30 on Wednesday, when Mr. Gambier Bousfield spoke from notes on the subject of "The Construction of Shop-Fronts During the Next Decade." A problem was being presented to architects, (an extension of the old question of the architecture of the shop front), which required considerable study and was a field worthy of earnest consideration by the profession. The requirements of trade necessitated in a good many branches the exhibition of wares and stock on every floor. The show window was not now confined to the ground floor, but every floor had to present a show window to the street. All the space that could possibly be spared from the necessities of construction was required for an area of glass on every floor, so that it would seem as if the only construction admissible was that of iron or steel and glass —the lightest and most economical as regards space. He did not think, judging from many buildings recently constructed in the city, that construction generally tended in the direction of economizing space. Buildings such as the Court House, Athletic Club, the Drill Hall, the Freehold Loan Offices and others were of very heavy construction, and the area occupied by the walls and piers very much limited the floor space within and the window space in the walls. No doubt some buildings required such massive construction; window space was not the absolute requisite that it is in shop fronts; but while we were practising such heavy construction the lighter kinds were likely to be overlooked. So far as existing examples were concerned, and there were many in the city to-day, there seemed to be but two methods of arranging such shop fronts of several stories as he was discussing. The general way was the rectangular method —upright and horizontal beams—and the other was a semi-circular arch thrown over the second story window. The problem that presents itself is how to adapt architecture to these requirements of trade. Formerly this question concerned only the ground floor; now every floor has to be similarly treated. Must we forever follow the lines of the Romanesque or be confined by way of variety to the round arch? Would it not be worth while to attempt some departure from these, which are becoming stereotyped forms, and in danger of endless repetition? The difficulties in the way of the application of gothic principles were well known; the point he wished to bring out was the necessity, not of adopting any period of architecture as a fixed rule for shop fronts, but of modifying the art to suit the requirements of the times.

Mr. Burke thought the problem presented by Mr. Bousfield's paper was one of the most difficult with which the architect had to contend, the combining of proper architecture with what was demanded by the requirements of modern trade; in fact it seemed to him an almost hopeless task if one desired to follow ancient models. He thought from the business standpoint the Chicago men had solved it as nearly as it was possible to do, having resolved their supports into simply iron stanchions with sufficient masonry to protect the iron from damage in case of fire. His experience with proprietors of retail establishments led him to almost dread any attempted solution of a problem of that kind. He had introduced one little window on Yonge St., which had pleased the proprietor very much, because it afforded the public a view into the basement as well as the ground floor, so that they could see the merchant's wares in the cellar. This

proprietor had told him that the basement was more valuable than the first floor, owing to the predilection of customers to go prowling down below rather than to go up, expecting to get bargains in the cellar that they would not find on the first floor.

Mr. Townsend said there was one point in the paper which he was inclined, though not very strongly, to object to. He referred to the suggestion that an attempt should be made to follow existing examples in work of this kind. He thought if the architect would look at the question more as a business problem, more as a practical question of putting up a building which, while it should not be positively ugly, would at the same time properly fulfil the requirements of the situation, he would arrive at better results on the whole than could be obtained by any attempt to work in a style that was formulated or that grew out of a different set of conditions.

Mr. Simpson asked if the difficulty Mr. Bousfield found was in the fact that business men wanted to make a show of their goods on windows above the ground floor. If it was desirable to get the lights above the ground floor as large as possible he thought it must be only because the architect's taste ran in that way. If it was desired to have the openings above the ground floor as large as possible it would be better to choose a style which lent itself to that treatment. If business men did not require to show their goods above the ground floor, and he could not see why they should, he did not think there should be much difficulty in getting sufficient light for displaying his goods in almost any style.

Mr. Langton said it seemed very much as if for commercial buildings pure and simple this was the problem of iron construction. It is being worked out in the United States by the aid of iron, but not as a problem in iron design. If the entire building is to be devoted to one purpose, and that a purpose requiring abundance of light, while as is usual the exterior wall area is so small that none can be well spared, he thought the architect would be judicious and would act most in the interests of his client if he seriously considered the question as an occasion for designing in iron. Where the upper part of the building was devoted to another purpose, such as offices, where very large windows are a discomfort rather than a gain, the problem became a complicated one for which he was not prepared on the spur of the moment to offer a solution; but he thought it probable that an artistic result would be obtained by continuing up the line of the slender supports in the lower storey and making the wall surface above by material and construction to be obviously only a filling in to reduce the window space.

Mr. Gregg thought the problem being discussed was a very old one. The practice of building thick glass fronts on the ground floor with a heavier building above was so old that it had almost come to be accepted, although architects could never agree that it was pleasing and right. We became accustomed to it in a one story building, and then it had come into Toronto in two story buildings. The Walker building was a very curious affair. The supports were probably fifty feet apart, and the space between light glass windows with partitions. Whether there was a support behind the divisions could not be seen, and what was presented to the eye was a very heavy stone front supported by two storys of plate glass. Of course that could not be accepted as high art, although it might be tolerated as what was demanded by the commercial requirements of to-day. The question was, if buildings of that sort were to be put up, should there be stone above the glass at all? Should not the same construction be carried through to the roof? He had seen an office building in Ottawa that he thought was a success in one way. Every office in the building had a plate glass bow window; the bow windows were carried up to the roof. It might not be pure architecture, but it had a pleasing effect, far more so than a building having glass below and stone above.

Mr. Bousfield said that some of those present did not seem to have quite understood him. Mr. Simpson seemed to think he was referring to a simple series of shop fronts on the ground floor. He thought everyone must have observed the increasing number of buildings on Yonge, King, Bay and Front streets, the proprietors of which were trying to expose their wares to view on every floor, making every floor a shop front. Mr. Gregg seemed to think the problem very old. Now he was not attempting at all to deal with the ground floor story of plate glass. But the whole front of the building was gradually becoming a front of plate glass, and probably iron, on account of the small space the latter occupied. Mr. Burke thought it was almost a hopeless problem to make it anything really architectural, and Mr. Townsend thought he meant that they should restrict themselves to these different styles. The problem was before them, and he thought if the architects did not attempt to solve it no one else would, and it was a nice problem for them as professional men to work out something which would be more really architectural than the everlasting horizontal lines that prevailed. He noticed that in some of the buildings where shop fronts were carried up only two floors, with the rest solid, they had arranged it by having a large central arch with two piers, one on each side, and then the arch above carrying the span over the whole. That plan and the horizontal lines seemed to be the only ideas at present being utilized. It would no doubt take a long time to work out the desired object, but unless the attempt was made, everyone who had a shop front built would stick to the straight lines or the one great central arch. He did not agree with Mr. Townsend that in a commercial building it was almost impossible to work out anything really architectural, and he thought it their duty as architects to make every building as architectural as they could, and if limited to certain forms of construction they should endeavor to make those forms as presentable and as architectural as possible.

Mr. Townsend thought Mr. Bousfield had not quite caught his idea; what he had tried to express was not that a building should not be architecturally correct, but that it was not well to try and compress modern requirements into forms that were the outgrowth of ancient requirements.

Mr. Burke thought he too had been misapprehended by Mr. Bousfield. What he had referred to in his discussion was the attempt to combine modern requirements with what are considered the best models of ancient architecture. With regard to the wall space above, he thought the only satisfactory way of treating it was by using the arch which was now to be seen in so many buildings, but the difficulty about the arch was that its haunches obstructed the light on that floor, and made it not nearly so valuable, although he thought it looked more correct constructionally.

Mr. Gemmell asked if the objection to the heavy front borne on a front of plate glass below had any force beyond a sentimental feeling? Did not the plate glass with the reflections of light and color look almost as solid as polished granite? He thought the attempt to get over the difficulty by the use of the arch was very much the weaker plan.

Mr. Belcher said the question at issue had been a source of perplexity to architects for the last thirty-five or forty years—the choice between art and the requirements of the businesses for which the stores were intended. Efforts had been made both in the old country and here to avoid this semblance of want of support in the upper storys, which he thought up to the present had been rather overdone. He feared that the requirements of trade would render difficult for a long time any satisfactory solution of the problem. He thought the large arch referred to did to some extent overcome the difficulty. In the old country the effort of the architect had been to make the supports as apparent as possible and to as much as possible avoid all sham, a course which he thought ought to be adhered to. He thought a building should be of such a character as to indicate the purpose for which it was intended.

Mr. Billings thought there was too much anxiety to make ancient examples fit modern requirements. He thought that was a matter of no consequence. If there was a problem to start with, it was far better to start de novo.

Mr. Paull said he supposed Mr. Bousfield when referring to buildings on Bay Street and King Street had in his mind the building on King Street opposite the Cathedral and one below Wellington on Bay Street. He did not remember any others where there was so much plate glass. It did seem to him that there was too much plate glass for the amount of iron built into the structure.

Mr. Bousfield said those were the buildings to which he referred, Oak Hall and a building on Bay Street.

Mr. Gregg said that in arranging for one Convention the proposition had been made that architects should submit photographs of their own work for criticism, and sit and listen to the criticism of them. That proposition had not been carried out. He would ask if it was right to bring up the name of a practising architect. He thought it was not. In the case of the Walker building the architect had passed away, and it was a perfectly legitimate subject of criticism.

Mr. Paull differed from Mr. Gregg on the point stated. And as to the Walker building, while the architect of the first building had passed away, the designer of the second was living.

Mr. Gregg replied that that was doubtless true, but that no doubt the architect of the second building was given an order for the replica of the first.

Mr. Townsend thought if the criticism was fair and honest it did the man whose building was criticised more good than anyone else. He would regard it as a compliment that any person should think his work good enough to stand criticism, and there was nothing he liked better than to go over his work and find where his mistakes had been made.

Mr. Gregg asked for a ruling of the question raised by him. The Association had yesterday repudiated something that approached a criticism of a government office, and he thought the present question was similar.

Mr. Paull remarked that the cases were not at all parallel. In the one case the architect had erected his work, and it had become public property, while in the other not only had he not erected the work, but it had not even been determined that the building should be erected, and the criticism was as to the architect's ability to erect such a building.

Mr. Simpson agreed in the proposition that it was not right to criticize a man's work and mention his name.

The President said it had always been admitted among themselves that one of the advantages to be gained by association was the comparison and criticism in a fair spirit of the work done by architects. Where criticism took the shape of pointing out what one man thought might have been accomplished in a better way than the one adopted he thought that was fair criticism, and he did not think anyone could object to having his buildings mentioned and his name as the architect. As Mr.

Paull had said, when a building was erected it became in a certain sense public property. It abstracted from the public a certain amount of the free light of heaven, and that being so it should justify its existence by being as beautiful as possible. He really did not think any exception could be taken to any of the comments that had been made that morning on any of the buildings referred to. It was very different with the so-called criticism which had yesterday been rebuked by Mr. Billings, which he did not think was criticism, but rather a sneer. He thought it was not well to be too sensitive about this matter of criticism where the criticism was fair and honest.

Mr. Gregg acknowledged his willingness to accept the ruling of the Chair, but pointed out that in the article referred to by Mr. Billings there was a distinction drawn, and he understood that under the ruling if the Association desired to spend half an hour in criticising the Canadian Building at the World's Fair they were quite free to do so.

The President replied that certainly if any member had any suggestion to make for the improvement of the Canadian or any other World's Fair building there was no objection. In regard to the question directly under discussion, it was certainly one of the most suggestive that could be brought before the Convention, and though an old problem, there were very few instances of its having been satisfactorily solved. He thought it might be laid down as an axiom that everything an architect handled should be treated architecturally. Unfortunately that had not always been recognized, but if ever architecture was to become again a living art it must be recognized. The difficulty in the past had been that generally shop fronts had been confined to the ground floor only, all the rest of the building being devoted to entirely different purposes, and treated in an entirely different manner. He remembered a building in Glasgow of which the ground floor front was plate glass with, for the period at which it was built, very slight supports, and the whole upper portion in the Scottish Baronial style, of a most massive character, with projecting gables, corbels and turrets, and everything calculated to give the upper part a very heavy appearance. Had it been cut off at the first story, or viewed from a window on the opposite side of the street in such a way that the lower floor was not seen, it might have been a thoroughly satisfactory design, but as it existed it was certainly antagonistic to all ideas of architectural propriety. He thought the most satisfactory treatment for these mixed buildings, where the fronts were narrow, was that pointed out by Mr. Burke, the large semicircular arch. It satisfied the eye, but the weak point was the apparent want of sufficient abutments. Where there were buildings on each side, that was not so noticeable. If it was desired to follow ancient models, plenty could be found in Italy. In the case of the Scaligeri tombs at Verona everybody could see that if it were not for the iron rods which keep the arches from spreading, they would all tumble to pieces, yet even Ruskin does not object to them. So that when the end piers were made to look as solid in design and material as possible, and the tie rod rather accentuated than concealed, it did not appear to be an objectionable method of construction. Another treatment he had observed was the making of the front like a frame, the support on each side carried up and the whole of the inside filled up with light iron and glass. He had seen some instances of that treatment which he thought were quite successful. Architects were very often denounced for not producing a new style, and if a new style was to be introduced he thought this problem was one of the fields in which it could be worked out. A few years ago the system had been adopted of building fronts entirely of iron. There were two objections to that. One was that the repetition of the parts necessary to secure cheapness became monotonous, and there was also always difficulty in attaining really artistic effects in such an intractable material as cast iron. The other objection was the danger in the event of fire, so he thought the front of the future would be on what might be called the American system, of steel or iron construction with the material encased in terra cotta or other non-combustible material. Instead of regarding it as a disadvantage that merchants at the present time called for plate glass in all their fronts, he thought it quite an advantage, because it removed the difficulty of having to provide much light below and less light above.

Mr. Langton, referring to the question which had been raised in regard to the criticism in the CANADIAN ARCHITECT AND BUILDER said the question had been cropping up at intervals, and he thought it was a very unfortunate thing. It was a matter in regard to which he would not say anything, but it had been said that the Association repudiated any criticism such as had been referred to as appearing in the CANADIAN ARCHITECT AND BUILDER, and that seemed to imply that that journal was to be muzzled because it was the organ of the Association. He did not speak with regard to the particular criticism complained of at all, and he had no doubt Mr. Mortimer would take in good part any criticism of that paragraph on the part of the Convention. But to say that the CANADIAN ARCHITECT AND BUILDER should never criticize any work done by members of the Association, seemed to him to be placing a muzzle upon the utterances of that paper in a way which was unworthy of the Association. The journal in question was the organ of the Association only in the sense that their announcements were published in it, and also with regard to any question of policy, such as that of making only members of the Association entitled to term themselves "architects," it was to be expected that the CANADIAN ARCHITECT AND BUILDER should concur. But if it should go out in the report that the fact that the paper was the organ of the Association had the effect of muzzling it entirely, and restraining it from indulging in any criticism of the work of members of the Association, he thought the result could not be one that was desirable. As to Mr. Fuller, he did not think there was an architect in the Association or in Canada who had not the greatest respect for his design, whatever he might think of the Canadian World's Fair Building. It was to be remembered that Mr. Fuller's reputation was not one that was yet to be achieved. Nothing that could be said could have the slightest effect upon his reputation, which was already established not by his past work only, but by work in progress at the present time, such, for instance, as the Toronto Armory Building, which all would acknowledge was a very fine piece of work. It was not a question of Mr. Fuller's reputation, but of a particular building. In the course of collecting material for the lecture upon the World's Fair Buildings which he was about to deliver, he had come across in an article by Mr. Van Brunt, a passage in which the United States Building at the World's Fair was criticized in very much the same terms as had been used in regard to the Canadian Building. The CANADIAN ARCHITECT AND BUILDER had said, as he understood it, that the function of the department to which Mr. Fuller belonged was to make designs for public buildings and carry them out in great quantity, and that the carrying out of such buildings as the World's Fair Building or a residence for the Governor-General was an innovation on their line of work, and an interruption to its regular course. He thought that was a fair enough view to take.

The President said the question was very simple. The CANADIAN ARCHITECT AND BUILDER or any individual had a perfect right to criticize fairly any building. He held that the article complained of was not fair criticism, and he thought the majority of those in the Convention would agree with him, but none of them would object to fair criticism from any quarter.

Mr. Power, while agreeing with the President that the paragraph complained of was not fair criticism, thought it would be a great pity to say anything which would convey to the editor of the CANADIAN ARCHITECT AND BUILDER the idea that it was not at perfect liberty to criticize the work of members of the Association.

Mr. Billings said he had felt it his duty to call attention to the way in which the paper in question was edited, and he did not think he had said anything not justified by the facts. There was no desire to muzzle the CANADIAN ARCHITECT AND BUILDER. What he had said was independent of anyone else. He felt quite sure Mr. Fuller would be quite willing to receive criticism at the hands of the CANADIAN ARCHITECT AND BUILDER or anybody else, so long as it was fair criticism.

Mr. Paull said he had seen very little criticism in the CANADIAN ARCHITECT AND BUILDER which he thought could be taken objection to, and in support of Mr. Mortimer he might say that two of the most prominent buildings in England had been the subject of very severe criticism, the Exhibition Building and the Houses of Parliament.

Mr. Gouinlock was in accord with the views expressed of the unfairness of the article complained of, and had thought at the time it was published that it was most severe. He was very glad Mr. Billings had brought it before the Convention.

Mr. Townsend proposed to offer a resolution to the following effect, "That while this meeting condemns anything in the shape of unjust or venemous criticism, it is the policy of the Association to court fair criticism upon any and all architectural work."

Mr. Gregg took a point of order; the question had been ruled on in most explicit terms, and therefore the question was settled, and there was no necessity to pass any resolution.

The President said Mr. Gregg had said practically what he was about to say himself. (Applause.) He did not think that under the circumstances any motion on the subject was in order.

Mr. Townsend said his only object in offering the resolution was to close the discussion, and he had much pleasure in withdrawing it.

Mr. Wright, of the School of Practical Science, then exhibited to the Convention, by the aid of the fine electric light lantern used in the School, a collection of views of the World's Fair buildings kindly loaned by Mr. A. W. Croil for the purpose. The plan of the grounds and of the various buildings was explained by Mr. Langton, as the views were exhibited.

At the conclusion of Mr. Langton's exhibition of views of the World's Fair Buildings the following discussion took place:

Mr. Burke:—The ground has been so fully covered by Mr. Langton that I haven't very much to say. I suppose one of the points of this exhibition is that it is the first exhibition which has been so rich in architectural art—a successful effort to produce a complete architectural symposium on a large scale. The buildings at other exhibitions were mainly buildings merely for the purpose of housing the exhibits, and of course, as Mr. Langton had already said, one of the reasons of the success of the

World's Fair Buildings has been the unity of the composition, and also that while the architects were rivals in a sense, yet it was a generous rivalry which produced harmony on account of the agreement as to scale, etc. I think one of the lessons gained there was that the classic style is capable of very grand effects when entered into as this scheme was entered into. I suppose that other styles of architecture could have been made as effective, but I think a greater time than was at disposal would have been necessary for the solution of the problem. Of course the architects who were chosen to design these buildings were men who had studied the classic, nearly all of them I think, at the French school, and they were familiar with the proportions and forms, and I think it was only for that reason they were able to produce the designs so rapidly and with such good effect. Of course if we entered into the study of detail there were many defects, but as said by Mr. Langton, the general effect was very satisfactory. Of course these buildings should be regarded simply as plaster models to a full sized scale of what these men could do if they had time. Of course the plaster model as a rule is very considerably modified when the finished work is produced. I think another lesson to be gained from the Exhibition is the value of sculpture. It has really been the first instance of the complete introduction of sculpture as an accessory in America. Mr. Montgomery Schuyler, who has already been quoted, has put the thing into very concise form when he ascribes the success of the Exhibition to three things—first, Unity; second, Magnitude; and third, Illusion. Unity, in the first place, enabling so many minds to produce effective buildings, because they were working all to the same scale. Magnitude, as Mr. Langton has so well shown, in the long vistas of these buildings, especially the Manufacturers' Building. Speaking of the magnitude, he tells a story of a Chicago man—not an architect; I am happy to say—who wanted the Manufacturers' Building taken down and placed on the lake front and re-erected, the reason that he gave being that it was "the biggest thing on earth." Without regard to the setting of the building as it was at present, he wanted it planked down on the lake front as a monument of the greatness of Chicago, regardless of the effect it gained from its setting and position in relation to the other buildings. I think another lesson is to be gained from the illusive effect. It has been a grand architectural scene provided for the enjoyment of the people. It was, as Schuyler says, Turneresque in effect—such a combination of views as Turner would have delighted in. I think there will be great danger in the future of uneducated architects endeavoring to reproduce some of these buildings on a small scale, the result of which would no doubt be failure. Perhaps men who have not seen the place at all or gained any conception of the surroundings, will see a photograph of some building and repeat it on a small scale, and be surprised that the effect he will get will not be anything like what it was in the original. I think if a taste for the careful study of classic architecture has been engendered by the examples set before the architects of the world it will be a grand step in advance, and will prove a wonderful help to the advancement of the profession.

Mr. Townsend:—I have been asked to make a few remarks as to the scale of the buildings, and I shall try to do so as shortly as possible. Mr. Montgomery Schuyler, in one of his admirable articles upon the Architecture of the World's Fair Buildings, says: "That it is a final censure upon the treatment of a piece of architecture which aims at overpowering the spectator by its size, *that it does not look its size*; as is the current and accepted criticism upon St. Peters;" and although I do not follow him in all his conclusions I fully agree with him in this. It is plain that one of the chief sources, if not *the* chief source of effect, or means of impressing the observer, at the disposal of the designers, lay in the magnitude of the buildings they were called upon to design, but I do not think the fullest advantage was taken of their unprecedented opportunities in this particular. It is true that the buildings were impressive by their size; a building over a third of a mile in length by half that in width could hardly fail to impress observers by its size; but I will venture to say that very few of the visitors to the Fair fully realized what those dimensions really mean. Few Torontonians, for instance, when looking at the Manufacturers' Building, realized that if placed upon the corner of King and Yonge Streets, it would about cover the parallelogram enclosed by Yonge, King, Church and Shuter Streets, and that all the buildings between Yonge and Church Streets from King right up to Bloor might be stowed away inside and still leave several millions of cubic feet to spare. Still fewer realized that the space between the water and the buildings on each side of the Court of Honor is about three times the width of Yonge Street.

We have seen,—Mr. Langton has pointed out,—that the landscape plan of the grounds, with its Grand Canal open at one end to the lake and crossed by lesser canals at right angles, presented a problem which could only be properly solved by a somewhat symmetrical treatment aiming at a general unity and, that, to secure this, two limiting conditions were agreed to—the adoption of the Classic style and of a module of 25 feet for width of bay and 60 feet in height of cornice. I think that it is generally agreed that the scale fixed by this module was admirably carried out. With hardly an exception the relative values of the buildings, their details and accessories were adjusted with marked skill. So cleverly indeed was this managed, that the discrepancy between the apparent sizes of the buildings and their actual dimensions was not brought home to the observer until he got inside and began to seek for the cause of the seemingly diminutive character of the exhibits, and of the innumerable expedients resorted to by the exhibitors with a view of overcoming the dwarfing effects of their surroundings.

I may be wrong, and I am not conceited enough to claim, that, in the merely cursory glance I have been able to give the subject I have found a means of attaining a result not reached by the united efforts of a board, composed of the most noted architects in the United States, but I cannot help thinking that still better results would have followed the adoption of a smaller module.

Just how much the module would bear reducing could only be arrived at by careful study and comparison with other buildings, and I have not given the subject sufficient study to be prepared with an opinion as present. But a reduction of 10 feet in height of the cornice line, while it would not have reduced the accommodation of the buildings in the slightest degree, would, if the figures given in the Official Guides are correct, have resulted in a saving of nearly three quarters of a million dollars in the buildings on the Court of Honor alone, and in my estimation would have materially assisted in the development of the magnitude of the buildings and intensified the impression made by it; by a still further repetition of the unit, i. e., the 29 bays on each half of the side of the Manufacturers' Building would be increased to 34; the 24 bays on each side of the Peristyle to 26, and so on, while the reduction in the size of the bays themselves would have been noticeable, only, in the apparently increased scale of the surrounding objects.

Mr. Gemmell:—The task was allotted to me of saying something of the impression made by the work of the Commissioner of the World's Fair, and I have taken the trouble to write something on that subject, which I will read:

I am expected to give some idea of the completed work—the effect of all the enterprise, labor and millions of money commanding the skill of the best men representing architecture in this generation of the United States—was the result such as they could congratulate themselves on as artists knowing good and evil?

To satisfy the average citizen of their own country was comparatively an easy task, he having too often been taught to admire as architecture the big, the brilliant and the costly in preference to the refined and true. But to attract the cultured of the old countries wanted a stronger and more subtle magnet, for to these the pilgrimage meant so much more of time and money, and to them art had ever dawned in the East.

My lodging determined that the 50th gate was my entrance to the World's Fair. I would like to have examined my copper plate ticket, but was hurried on by the stream of humanity and found myself in a by-street of the White City, devoted to State buildings and those of Foreign Governments, the prevailing impression of which was wonder at the luxuriant costly way in which they were doing their tenting of a few short months. Brazil, now fighting over their inheritance, was here like a prodigal wasting her substance in a far country. The rich pile carpets on her staircases were worn in places right through by the countless feet that thronged up and down all day long.

A large number of the State buildings exhibited what some time ago was the general characteristic of American architecture, the original and picturesqueness at all cost. But many others were fine examples derived from the proper study of architecture, and this not confined to the older States; the New York and the Colorado Buildings were in the same Italian Villa style, and I liked the latter the best of the two. There also lingers in my memory the quaint California Building and the Roman Villa of Vermont—the former for its striking and dignified effect, gained by such simple means as massive wall spaces, deep reveals and red tile roof and heavy eaves. The Roman Villa rivetted the attention by its quiet taste, with its open court and fountains bespeaking a delightful home life under a clear sky and balmy climate, which must have required may years of peace and plenty to foster and enjoy it. The ancients evidently were not always at war and fighting, as we are apt to gather from our histories.

I noticed also the French Pavillion, somewhat coarse I thought on the exterior for that artistic nation, but with a beautiful shady court, having colonnade all around and steps down to the garden, embellished with bronze statuary and refreshing pool of running water.

The German Building, a mediæval Town Hall, striking and picturesque; although you liked it you could not get over it that there was something barbarous about its outlines and definite color decorations. The interior I heard afterwards was a series of old art revivals that I should not have missed.

In my first day's walks I occasionally caught glimpses of cornices, pillars and perhaps a corner tower in the distance of pure white, and of grander proportions than those around me, which gave hint that I was not in the heart of the city of which I had heard so much. I did also see the Art Gallery with its stretch of water in front reflecting as pure refined a building as ever adorned the Acropolis of Athens. But you had to fix your gaze on it and its immediate surroundings, there being much in the vicinity out of harmony with its extraordinary dignity and repose. The approach from the water was very impressive. By a flight of many steps, with noble lions pedestalled to right and left, you reached the heroic statue of Minerva which marked the centre of the main door.

It was on the second day that I found myself on a bridge across a canal that led into the basin, the one with the great bears on it, and I do not think in all the Fair there was a more favored point of view, one that gave the picture in so many varied, everchanging and beautiful perspectives, as you endeavored to survey the whole. The clear blue waters of the lake had been let into a grand basin and

wide canals running into it, the margins of all parapeted as if in solid stone. Graceful bridges whose piers and abutments looked very real, statuary of men and animals, not at random, but marking a landing stage or the approaches to a bridge; broad smooth ways, steps and terracing, exotic plants in urns, accented balustrade and parapets. For beauty the surface of the water had aquatic birds, plants, and gondolas for use, noiseless launches driven hither and thither by stored electricity with the speed and ease of fishes. The grand basin was indeed a happy thought. By it you were constrained to take the perspective at a proper distance, with always a beautiful foreground. Such would not have been the case with a stretch of ground dotted by a restless populace, however finely it might have been laid out. Around the basin at magnificent distances rose the buildings you have heard spoken of in detail. Describe the impression made by these, I cannot. I could tell you what you all know, that here the dry bones of our studies in the "orders" of Greece and Rome were made to live in the most graceful fashion and form a fitting enclosure for the greatest spaces man has ever protected from the elements, and added to this such embellishments of tower and dome as wrought out by later times. On this solid basis the buildings rose as one harmonious whole, with no jarring rivalry of men and styles. All this and much more would fail to give you an idea of this scene—a panorama conceived and carried out as genius only can.

If armies in times of peace require their reviews and parades, what a necessary field-day was here for architecture, to keep our ideals pure and high in our utilitarian age! Let me suggest to the authors of the World's Fair, the grand basin itself as a symbol of their work. Viewed at the Administration end, all is life and movement—the figures around the gilded dome, the splashing fountains and terraces of water, Father Time and the Amazons on McMonnies Barque, tritons, horses and dolphins, all in a fever of activity. The opposite end, the task accomplished—the golden goddess, well pleased, looks neither to the right nor left, ready to receive the deserved homage of the nations, and behind her the stately peristyle, albeit of no use but to render the precincts of the lovely Court of Honor sacred from sight of aught unseemly, or only seen softened through the vistas of those beautiful columns.

Take it all in all, we never shall look upon it's like again. I would go further and say, that the world in all time has never had such another aggregation of great buildings with the opportunity of disposing them to give grandeur of effect. Whatever may be said elsewhere of incongruity around the grand basin, where the sway of the commissioners reigned supreme, let the eye roam as it will there was nothing to startle as out of harmony with the whole. Could this ever be said of any square in Europe, ancient or modern?

What a pity it was only for so brief a season. Perhaps! But I have gazed on Paris, Venice, Rome; I do not expect to see them again: the impression of the White City is none the less real because I cannot see it again. Is the glory of its architects to be disparaged because it was built of perishable material? Was not also Athens, Rome, Carthage? The City of Alexandria and its great library perished by fire so also did the beautiful peristyle.

Mr. Gouinlock:—I have been asked to speak on the materials used in the erection of the World's Fair Buildings, but it unfortunately happens that it is a subject to which I have given little attention, yet though I feel particularly ill-qualified to treat of the question, I am willing to make the attempt, feeling that however dismally I myself may fail in imparting any knowledge of the subject, my efforts will be the means of bringing out a fund of valuable information from others more capable and better posted. That each one of this magnificent cluster of buildings had to be designed to suit exactly the special purpose to which it was to be devoted, and that, therefore, such constructional material had to be selected as would amply sustain any strain it might be called upon to bear, was a matter of course.

That the buildings ought to be individually handsome in appearance was equally a matter of course, and that they should present collectively a grand spectacular effect was evidently aimed at, with what wonderful success no one who did not pay a visit to the Fair can even faintly realize.

But, while the buildings had to be strong and beautiful, it was not desired that they should be lasting. Had they been required for the enjoyment of posterity, no doubt the architects who devised the scheme would have preferred stone and marble, but in this case of course, there was no more need for such expensive material than there would be for a theatrical scene; effect and not durability being the object.

The trusses and frames were therefore erected in such reliable if prosaic materials as iron, steel and wood, apparently elaborate work of engineering rather than architecture, of science, than of art.

But now art with her fairy wand, or rather "staff," appears, and the labyrinth of dry facts has become an enchanted city of surpassing loveliness to be enjoyed for a day and to be remembered only in dreams. The composition known as "staff," invented for the express uses of the Paris Exhibition, is composed of plaster and hemp or other fibrous material, and being quite flexible, can be easily secured by nails or other ways, but the extraordinary extent to which it was used in the Fair Buildings, sculpture, etc., and the wonderful success with which it was employed, leads one to regard it as among the possibilities of the future.

Whether it could be used with advantage in works intended to endure is one of the many phases of this question of World's Fair material upon which I am unable to venture an opinion.

Mr. Gambier Bousfield moved a vote of thanks to Mr. Langton for his very interesting talk on the subject of the World's Fair Buildings, which had been such as to enable those who were not at the World's Fair to gain such impressions of the huge scale upon which it was carried out as they could not have obtained in any other way. The remarks of the other gentlemen who had taken part in the discussion he thought were also very helpful. It seemed to him a matter of regret that such a group of buildings could not have been maintained permanently, but at the same time there was reason to be thankful that there remained in other places groups of buildings of a more enduring character to serve as exhibitions of the wonders of architecture to the present day. Such were the sites of Athens, ruined as they were, and Rome and London. But although the buildings of the World's Fair were to be removed, the lessons to be learned from them would remain forever.

The President said Mr. Langton and the other gentlemen who had taken part in the discussion were to be thanked for the trouble they had taken and congratulated for the pleasure they had afforded. The best general description of the impressions produced by the Fair that had come under his notice was probably in the grounds of the Fair itself. He had met a gentleman there one day bubbling over with enthusiasm and almost as full of liquor, who, steadying himself as he gazed on its wonders, burst forth with the exclamation, "Must all this glory vanish?"

After lunch, which was served in the building, a paper was read by Mr. A. P. Coleman, of the School of Practical Science, on "Rocks," a synopsis of which will appear in our March issue.

Mr. Darling moved that a vote of thanks be accorded to Mr. Coleman for the highly instructive and interesting paper he had just read. The only thing to be regretted about it was, that it did not continue longer.

Mr. Power said he had great pleasure in seconding the motion; he thought every one present had been delighted. He hoped members would not fail to send specimens that might come in their way to Prof. Coleman.

The president said he had much pleasure in conveying the thanks of the Association to Prof. Coleman for the very excellent paper with which he had favored them. It was sometimes said that gratitude consisted in a lively sense of favors to come. That could not be said in this case, however, as it was not the first time they had been entertained by Prof. Coleman.

Mr. Power then read a paper entitled "Some Points on Building," the publication of which is necessarily deferred.

This was followed by a paper from Mr. Simpson, on "The Architect," which will be printed in a later issue.

Mr. Burke said that one text which might be taken from the standpoint of the committee that had prepared the programme was the fact that Mr. Simpson was one of the younger members of the Association who had kindly come to their aid and prepared this very interesting paper. There had always been considerable difficulty in inducing the younger members to take part. He had been assured by Mr. Simpson that he had himself derived very great benefit and pleasure in the course of preparing the paper. Mr. Burke thought the Association owed a debt of gratitude to Mr. Simpson for thus coming forward and assisting to make the programme interesting.

Mr. Gouinlock suggested that the council endeavor to get resident and non-resident architects to send in photographs of what they considered their best work to be exhibited at the next convention and submitted to criticism. He thought the more criticism they were submitted to, especially the younger members, the better.

The President thought the suggestion a good one, and well calculated to have a tendency to improve the tone of architectural design.

Mr. Bousfield added that if anyone had any special work, such as railway stations, that they should send it in, with the reasons for special features designated.

Mr. Darling agreed in thinking the suggestion a good one. He thought that an atmosphere of criticism was wholesome, and the meetings would be more interesting and profitable if there was something of the sort. It had been tried at the Guild. Nobody felt at all the worse for it there, and the Guild as a whole was much the better.

Mr. Helliwell then read a paper on "Current Styles," which was illustrated by magic lantern views given by Mr. Wright, of the School of Practical Science. This paper will also be published in a future issue.

At the conclusion of Mr. Helliwell's paper Mr. Gray said it must be very evident that nothing had lent greater interest or given greater practical value to the convention than the magic lantern exhibitions so kindly given by Mr. Wright. He had therefore much pleasure in moving a very hearty vote of thanks to Mr Wright for his many courtesies and the beautiful exhibitions of views he had given. (Applause).

The President said the sentiments expressed by Mr. Gray must be shared by everyone present, and he felt great pleasure in tendering the thanks of the Association to Mr. Wright.

A vote of thanks to Mr. Helliwell for his paper was then carried on the motion of Mr. Belcher, seconded by Mr. Edwards.

The Association then proceeded to the election of members of the Council. The gentlemen elected were Mr. Thomas

Fuller, Ottawa, Mr. H. B. Gordon, Toronto, and Mr. J. Gemmell, Toronto.

The following votes of thanks were then proposed and carried:

To the Hon. The Minister of Education, for the use of the room in which the Convention was held.

To the Auditors, for their labors in auditing the accounts.

To the President, for the able address presented by him this year.

Mr. Langley and Mr. Gregg were then appointed Auditors for the year.

The President then declared the Convention for 1894 adjourned.

THE DINNER.

The annual dinner was tendered, as usual, by the resident to the non-resident members, at Webb's restaurant, and at the social board a few hours were pleasantly spent.

Among the guests were Professors Galbraith and Coleman, Messrs. C. H. C. Wright and T. R. Rosebrugh, of the School of Practical Science.

A few informal toasts were proposed and honored. Mr. Burke in proposing "The Profession," referred to the efforts which had been put forth to obtain legislation by which the word "Registered" would no longer qualify the word "Architect" in the Architects' Act. He urged the members to stand by the Association and the objects it was seeking to attain. While there was reason to deplore the apathy of some of the members, the excellent character of the meeting which had just come to a close, was a subject for congratulation. The main object of the Association should be the education of the rising generation of architects.

Mr. Curry, in responding, referring to the difficulties in the way of the Association, said that it was well to have obstacles to overcome, necessitating the putting forth of effort. Those qualified by education should alone be allowed to call themselves "Architects." The civilization of the present day demanded proof of competency on the part of both the professions and the trades. The Association should be maintained whether the desired legislation is secured or not, on account of the benefits resulting from the better acquaintanceship of the architects themselves and the removal of petty jealousies.

Mr. Langton proposed a toast to "The School of Practical Science," and took occasion to express appreciation of the advantages derived by the Association from contact with the School.

Prof. Galbraith, in reply, referred to the Geological and Architectural departments of the School, and said that as a school they were sufficiently interested in architecture to wish that the profession might be made a close corporation. Only by this means could the standard of professional work be maintained, which formerly was done by the guilds.

Prof. Coleman said the world was full of artists, good bad and indifferent, but the public was placed under no obligation to look at their work. With architecture it was different. The work of the architect is exposed to view on the public thoroughfares, not temporarily, but for a period of many years. It must be looked at. Nothing so affects for good or bad the taste of everybody, therefore the government should as far as possible impose such conditions as would prevent the erection of architectural abortions.

Mr. C. H. C. Wright stated that the Association had been a benefit to the School. As yet they had only a poor collection of photographs representing the architecture of the province, and he would be pleased therefore if the members of the Association would send him photos, drawings, etc., from which lantern slides could be made and a permanent collection formed. Where required these photos and drawings would be returned to their owners after being retained for a few days at the school.

Mr. Rosebrugh, Lecturer in Electricity, also responded briefly to the toast.

Mr. Jarvis remarked that as there was only here and there a young man with the qualifications of a successful architect, he hoped the Architectural Department at the School of Science would endeavor to discourage those students who had no natural aptitude for the profession.

Mr. Gouinlock in suitable terms proposed "Our Guests."

Mr. Power in responding adverted to the success of the Convention just held, and urged effort on the part of those present to increase the membership of the Association.

Mr. Belcher responded with a song.

Mr. Billings thanked the Association for having elected his chief, Mr. Fuller, to a position on the Council.

Messrs. Edwards, of Hamilton, and Kinsey, of Port Elgin, commented upon the fact that while some outside members had come long distances to attend the Convention, many of the members resident in Toronto were conspicuous by their absence.

Mr. Kennedy, of Barrie, replied briefly.

Mr. Burke expressed his pleasure at seeing present the first graduate under the Architects' Act, Mr. Baxter, of Stratford.

Mr. Baxter, in reply, said that for 99 per cent. of what he knew about architecture he had to thank the Association, and he strongly urged upon architectural students the advantage to be derived from submitting themselves for examination. The Association, he was sorry to say, was not as well known as it should be throughout Western Ontario. He was sorry also that there were no other members from west of Stratford present.

Mr. Curry, in responding to "The Council," congratulated that body upon the election of three such capable men as had that day been added to their number. For himself, he had been connected with the Association in an official capacity ever since its organization, and now for the first time found himself in the position of a private member.

The health of the retiring President, Mr. D. B. Dick, was enthusiastically received, accompanied by expressions of appreciation of the ability and faithfulness with which as President he had served the interests of the Association.

Mr. Dick, in reply, said that he had done his best for the Association, especially in connection with the examination of students. As a means of awakening a greater interest in the Association and a wider knowledge of its objects, he hoped that the new Council would arrange for a series of lectures to which the public should be invited.

The toast to "The Press" was acknowledged by Mr. C. H. Mortimer, of THE CANADIAN ARCHITECT AND BUILDER, and "The Ladies," by Messrs. Connolly, Jarvis and Sproatt.

At intervals, during the proceedings of the evening, songs were sung by Messrs. Gouinlock, Connolly and Belcher.

A great deal of amusement was afforded also by the clever ventriloquil performances of Mr. Simpson.

BUILDING MATERIALS IN THE NORTHWEST.

BELLEVILLE, ONT., Feb. 9th, 1894.

Editor CANADIAN ARCHITECT AND BUILDER.

SIR,—Circumstances have given me an opportunity to visit the North West Territory and examine the building materials in that part, which may be interesting to many of the readers of the CANADIAN ARCHITECT AND BUILDER.

During the past year I have been under a contract with the Dominion Government to build a post office at Calgary, which placed me in a position to notice and examine the resources in that part of the country in the way of material for building purposes.

What will strike a visitor to Calgary as being marvelous is the solid appearance of the buildings erected there, for stores, banks, hotels and the new public building. The reason for this is, they are built with a sandstone found in abundance in that locality, very easily worked to any design, and which gives the whole structure a solid substantial appearance, and the use of which the Department of Public Works has not been slow to encourage. Although no improved appliances have been introduced into the quarries, I have seen some large stones quarried. My men quarried a stone of the following dimensions: 18 ft. long, 8 ft. wide and 3 ft. thick. When first quarried the stone is very soft, of a buff color, with a green tint, but soon hardens by exposure. I have seen tombstones and monuments worked out of this stone, to designs which give an excellent appearance. The lime is white, and the quality is equal to any I have used in Ontario. There is also slate used for roofing, of a very good quality, brought from New Westminster, B. C. Lumber, lath, etc., is furnished at about the same prices as in many parts of Ontario.

I have no doubt, that with such materials in abundance, in a few years some of our best monuments of architecture will be found in the Alberta districts. I also believe a great future is in store for that part of the country, with its coal mines to be found all over for hundreds of miles, also iron beds, water in abundance, and the lands of the best. Just now the demand is limited for the materials I have named, but with better railway facilities it will be sure to increase, and in a few years that country will be better known and appreciated.

I do not write this to induce mechanics to go there; that is not the class wanted, but men used to agricultural pursuits cannot fail to do well. But, my object in sending these few lines is to inform your numerous subscribers what that part of our great country produces in our line of business.

Yours, etc.

WALTER ALFORD,
Contractor, etc., Belleville, Ont.

COMPETITION.

THE competition for designs for a library and museum for the city of Milwaukee, Wis., has been decided in favor of Messrs. H. C. Koch & Co., of Milwaukee. Seventy-four designs were submitted, from which Prof. Ware, the expert, selceted five as the most suitable, and of these five the committee gave Messrs. Koch & Co.'s first place. Messrs. Gordon & Helliwell, of Toronto, were among the competitors in this competition.

PUBLICATIONS.

We are indebted to the Potsdam Red Sandstone Co., of Potsdam, N. Y., for a copy of their artistically designed and lithographed calender for 1894.

The Cosmopolitan for February introduces a famous European author to its readers—Valdes of Madrid, and the artist Marold, of Paris, well known as a French illustrator.

Mr. Fred. P. Spalding, assistant Professor of Civil Engineering in Cornell University, is the author of a work of 100 pages, which has just reached our table, entitled "Notes on the Testing and Use of Hydraulic Cement.' Price, $1.00, bound in cloth.

Encouraged by the compliments bestowed upon their calendar of 1893, the B. Greening Wire Company, of Hamilton, Ont., have issued a handsome and serviceable calendar for the present year. It is printed in four colors, the blank spaces being filled with illustrations of the manufactures of the company, and on the back, are given a number of reference tables.

ILLUSTRATIONS.

C. A. & B. COMPETITION FOR A TOWN HOUSE AND STABLE—DESIGN SUBMITTED BY "GOTHAM" (MR. A. E. WELLS) AWARDED FIRST POSITION.

This design is for a house of frame construction on a foundation of stone. By the arrangement of the lot, light and air are obtained on three sides of the house. The dining-room is benefited by the morning sun, and the kitchen has cross ventilation. Serving pantry and bath room have abundant light; and the position of plumbing fixtures on both floors renders possible a simple and cheap system of plumbing. The detail of stair case hall indicates the general character of the interior wood-work. The exterior of the house shows walls and roofs hung with shingles. Leaded glass, such as is indicated on the front elevation, besides being a pleasing external feature, might be made to contribute to charming interior effects. The stable is in construction, similar to the house. The accommodation here required has been provided for and this adjunct of the house made as simple and unobtrusive as possible.

OLD HOUSE AT BRUNSWICK, GERMANY.

RAILWAY STATION AT DUDDSWELL JUNCTION.—STRICKLAND & SYMONS, ARCHITECTS.

BREWERY BUILDING, MONTREAL.—DUNLOP & HERIOT, ARCHITECTS.

THE CONSTRUCTION OF HARDWOOD DOORS.

In constructing the modern hardwood door, a series of operations are gone through by the joiner which are extremely interesting and of value to those who desire to know something of the method of construction employed in completing this now universal detail, writes Owen B. Maginnis in the *Building Monthly*. These operations embody a number of systems of proceeding, each aiding to a final end, and are as follows:—The first process is to glue the cores or grounds together. These generally consist of kiln-dried white or yellow pine, say 1½ inches thick for a 1¾-inch veneered door, the veneers being ⅛ of an inch thick. The cores are generally got out full enough to allow for facing and thicknessing on the jointer and in the planer. The number of pieces in the cores depends on the desired width of the stile or rail, as, for instance, a 6-inch would require a ¾ inch band of the necessary hardwood, ash, oak or walnut, as specified, and four 2¾ inch pieces of pine. In glueing these cores together they are carefully jointed with the plane and scratched, then heated in the hot box and at once glued, being pressed tightly together with large handscrews, in order to squeeze out the superfluous glue and close the joints.

In making joints in veneered work, the surface of the joint must in all cases be (a little shaving) hollow, for the purpose of allowing the outer arises to come close together. Of course, all the cores should be long enough to make the necessary height, as 7 ft. 9 in. long for a 7 ft. 4 in. door, and so on as needed, always allowing enough to round over the bottom ends, so that the veneer will not be torn off when moving the door. When the glue is set the surfaces are scraped off clean, and they are faced up perfectly out of wind of the jointer and afterwards tried up true with the try plane. This being done the stiles and rails, which are built up in the same manner, are brought to the planer or planing machine and there thicknessed. The stuff cores are then brought back to the bench, where they are surfaced as before with the try plane (to remove all lumps) and scratched with the scratch plane to form a keying for the veneer. All knot holes or flaws which might be liable to cause a defect in the veneer are carefully filled up to ensure good veneering. This being done, it is usual to prepare the veneer after it has been ripped to its necessary width and crosscut to its length—that is, the different pieces for the stiles, rails, muntins, etc. It is usually prepared by smoothing the poor side (being very careful that it is entirely free from spots or shakes, little knots or other flaws) and scratching it thoroughly to ensure a firm keying for the glue. All the pieces (which generally run from ⅛ thick up to ½) are placed between strips edgeways in the hot box, and allowed to become thoroughly impregnated with the heat, so as to keep the glue from cooling, besides opening the pores of the wood to admit it. While the veneers are in the box the cores are placed (the stiles first, in pairs) on the glueing horses and the big handscrews set ready for applying, keeping the jambs wide enough apart to take in two pairs of 2 inch stiles, or eight inches, or six inches, for one pair of 3 inch, and so on as required. When the veneers are sufficiently heated the flat faces of the cores are glued both sides and turned up on their edges (hardwood strip side up) slightly apart, and the veneers are dropped between.

Be sure, however, to have the points of the grain up, to have the grain running up, and to have the grain so that they will pair alike. This should always be done before placing the veneers in the box. Having placed the cores of the stiles on the edges to which the hardwood strips are affixed, the woodworker takes his veneer and, after carefully matching the grains, places them grain points up with the scratched side towards the glued faces of the cores resting on the horses, so that the edges of the veneers and cores will come fair. He will then place a veneer on each of the right and left outer surfaces of the cores. Having done this, he places a crawl or piece of 1¼-inch stuff on each outside to press the outer veneers against their ground, and takes the big hand screws which have been set to span the combined width of the cores and veneers. He places one at either end about two inches from the end spaces, the rest eight or ten inches apart, applying each screw from opposite sides. He screws the inner throat screw till it grips on the edge, and then turns the outer lever screw solidly down on the crawls, thus pressing the surfaces tightly together and forcing the glue into the scratches, at the same time driving out that which is superfluous. Before the screws are permanently screwed tight, the whole mass is turned up to see that the veneers completely cover the whole width of the surfaces and, if they do not they must be driven to their places with a block, taking care not to bruise or break the edges. Be certain, too, that the screws are all right and the veneers pressed to a perfectly close joint. It is best for two to veneer, for one can regulate the veneers while the other is applying the screws, and both can act together on the screws afterwards, giving more power. The glued stiles or mullions are then left in the screws about five hours to allow the glue to set. Let me here impress the fact that the stuff must in all cases be thoroughly heated, and the glue perfect glue (about one-third water and two-thirds glue) laid on quickly with a large soft brush from a large pot, also that the operation be rapidly done before the stuff has time to cool. The crawls must be only the exact width of the stuff and no wider. It is advisable that the jaws of the hand screws be also wide enough to reach across the width.

SHAVINGS.

In wrought iron, such as railings, grilles, etc., perhaps no paint is so effective as a perfectly dull black.

It is reported that the Stanstead Granite Company have disposed of nearly $40,000 of stock, under their new charter.

The Record Foundry and Machine Company, of Moncton, N. B., are about to engage in the manufacture of iron and steel bridges.

Messrs. Edmund Burke and S. H. Townsend have been appointed to represent the Toronto Architectural Guild on the Toronto Technical School Board.

The Sanitary Association of Hamilton, Ont., is urging upon the Mayor and Council of that city, the necessity of employing an inspector of plumbing.

On the 21st of January, the new First Presbyterian church lately erected at the corner of Dufferin and Park avenues, London, Ont., was opened with appropriate cefemonies. The building is of red pressed brick, and cost about $25,000.

Mr. John Sykes, of Oshawa, is handling largely British Columbia shingles, and expresses the opinion that an increased trade can be done in the manufacture of doors, sash and blinds.

Mr. R. J. Davidson, upon severing his connection, extending over a period of twenty years, with Thackery's planing mill at Ottawa, was waited on by a number of contractors, builders and employees of the mill, and presented with an engrossed address and a handsome gold watch.

We learn from the Metal Worker, that Messrs. Merchant & Co., of Philadelphia, have recovered heavy damages against a contractor for having used ventilators which were claimed to be infringements on their Star patents, in the Lincoln, Neb., Hospital for the Insane, where it was specified that the Star ventilator should be used.

The new building of the Toronto Athletic Club was formally opened last month, and was visited by several thousand citizens. It is excellently adapted in all its appointments, for the purposes of recreation and physical improvement. The cost of the building approaches $100,000. Mr. E. J. Lennox was the architect.

In an action brought against the city of Toronto recently, by one Harman, for injuries received in falling from a scaffold while working at the city swimming baths, the defence entered by the City was, that as the plaintiff had built the scaffold himself, he alone was responsible for his injuries. The defence was upheld by the court, and a verdict given in favor of the city.

The British Columbia Shingle Manufacturers' Association has been formed to regulate prices, and otherwise promote the interests of its members. A local paper states that shingle bolts cost $4.00 to $4.50 per cord, that it costs $1.30 per thousand to produce shingles, and that the very lowest price at which shingles can be put on board cars at Vancouver, is $1.50 per thousand.

Mr. Peter Redpath, the well-known philanthropist, of Montreal, died in that city, on the 2nd inst., at the age of 73 years. Mr. Redpath donated to McGill University, in 1880, the Peter Redpath Museum, and in 1891, the Peter Redpath Library Building. He also gave $20,000 as an endowment to a chair of natural philosophy, and $10,000 for expenses and improvements to the Museum, besides over three thousand volumes, comprising the Peter Redpath collection of historical books.

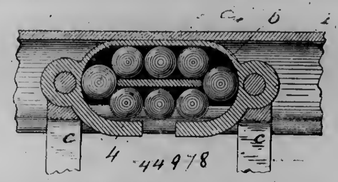
Mr. Chas. Baillargé, City Engineer of Quebec, has an interesting article in a recent number of the Engineering Record, on the "Fall of the Louisville and Jeffersonville Bridge," a subject which has largely engaged attention of late in the columns of the American engineering press. In the article reference is made to the circumstances connected with the landslide at Quebec several years ago, an illustration of which was kindly furnished to this journal by Mr. Baillargé, at the time of the occurrence.

Alexander Potter, C.E., Assoc. M. Can. Soc. C. E., 137 Broadway, New York city, has been awarded second prize of $500 for the best design of a new system of waterworks for Evansville, Ind., a city of 80,000 inhabitants. Twenty-two plans were submitted by engineers from all parts of the United States. Mr. Potter, who is a Canadian, began his engineering studies under City Engineer Keating at Halifax in 1883, and was the youngest competitor, having graduated at Lehigh University in 1890 at the age of 24.

A great deal of interest has been aroused by the discovery in Toronto of what is alleged to be a picture painted in oil by Raphael when twelve years of age. The subject of the picture is the Mosque Della Grande. On the back of the canvas there are three inscriptions, which read as follows:—"Painted at Urbino by Raphael, when aged twelve years, being the interior of the Mosque Della Grande." "Taken from Holyrood in 1688 by Lord Russell." "To the Lady Arabella Russell in the year of our Lord 1739 (or 1789)." Below the last inscription is the single word "Raphael." The existence of the inscriptions was revealed by the picture falling out of its frame, the frame having previously covered the writing. The picture is 22 inches wide and 26 inches deep, and is owned by Miss Annie Lackie, 58 Shaftesbury ave.

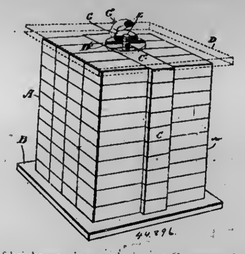
RECENT CANADIAN PATENTS.

A patent No. 44,917, has been granted to James Thomas McCabe, of Toronto, Ont., for a travelling hanger for doors, curtains, etc., the principal features of which are: the combination of a track composed of a tube having a longitudinal slot formed therein, and bearing surfaces arranged on



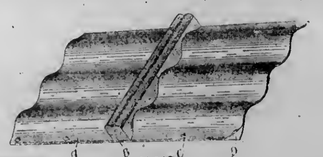
each side of the slot, bearing balls running upon the surfaces, a carriage supported by said bearing balls, a depending arm from the carriage, and means for detaching the depending arm to the object to be supported. An illustration of the device is given herewith.

Thomas Parker, John E. Wright, Francis F. Stuart and Alexander M. Colquhoun, of Toronto, Ont., have been granted a Canadian patent, No. 44,896, for a shipping device for bricks and similar articles, consisting of a top and bottom board, central bolt passing through a central opening



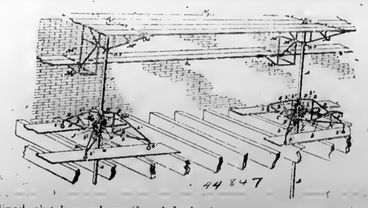
within the pile of bricks—a ring or clevis nut G1 screwed on to the top of the bolt and top and bottom washers D , and B , surrounding the bolt and situated between the nut G, and the head of the bolt respectively, as shown in the accompanying illustration.

Hugh Silver, of Lindsay, Ont., was on the 11th of December last, granted a Canadian patent, No. 44,869, for a wood wall covering, which consists of the combination with a wall or similarly substantially flat



surface, W, of sheets of veneer, A, corrugated in line with the grain thereof, and having some of the bottoms of the corrugations nailed to wall, and a moulding B, whose under surface fits the corrugation, set over the joint between the sheets, as per illustration.

A Canadian patent, No. 44,847, for a builder's scaffold, was granted on December the 9th last, to John Elzear Ennis, of Duluth, Minn. The invention consists of a combination with a main frame or support, of a shaft movable vertically in frame, a platform bracket supported on the upper end of the shaft to turn thereon, and a clutch mechanism located within the main frame, engaging the shaft, in combination with the shaft A, of the lifting mechanism, consisting of yoke C, lever D, pivoted therein, oppositely



inclined clutch members G and J, having screw shanks projected from opposite sides thereof, link arms E and E , screw nuts F, and detachable weights; the combination with the shaft A, and the bracket Mx, supported thereon, consisting of an upper section M, a downwardly extending portion M , and an outwardly extending section M2, the plates P, having concaved portions adapted to fit the bearing bars of the said bracket, and upwardly projecting lugs P1, and the planks held on the said plates P, as shown in illustration.

The second edition of the December World's Fair Cosmopolitan brings the total up to the extraordinary figure of 400,000 copies, an unprecedented result in the history of magazines.

USEFUL HINTS.

The paint on the outside of a brick wall 30 feet in length and 20 feet in height of a warehouse in New York came off after a year's exposure; in another year the hard bricks of which the wall was built began to crumble. The cause, which for some time was a mystery, was eventually found to be a large quantity of salt in burlap bags stored behind the walls. Although thick boards intervened at places the salt had thoroughly impregnated and destroyed the solid brick wall, and therefore the oil and paint.

GOLD LACQUER.—For making gold lacquer for metals, the following formulas are recommended: 1. shellac, 100 parts; alcohol, 895 parts; boric acid, 5 parts; picric acid, enough to color. 2. dragon's blood, 7½ parts; gamboge, 40 parts; mastic, 30 parts; sheellac, 30 parts; elemi, 7½ parts; sandal-wood, 20 parts; sandarac, 20 parts; venice turpentine, 15 parts; alcohol, 850 parts. 3. shellac, 120 parts; gamboge, 30 parts; mastic, 30 parts; sandarac, 60 parts; aloes, 10 parts; venice turpentine, alcohol, 750 parts.

An experiment with two bars of iron separated by a layer of charcoal and subjected to an electric current of fifty-five amperes at two and a half volts has resulted in one bar, the cathode, being converted into steel on the side next the charcoal, while the other bar, the anode, remained unaffected. This was after three hours of heating under the current, and is one of a series of experiments carried out recently by M. Garnier, which are likely to lead to better understanding of the principles underlying the process of converting iron into steel.

TO MOUNT PHOTOGRAPHS WITHOUT BUCKLING.—The satisfactory mounting of photographs is a troublesome operation, and the following suggestion from a contributor to the *Outlook* may be of assistance to amateurs: I have found a method by which a photograph or engraving can be mounted on the thinest paper without curling or wrinkling. If the picture is a photograph it should be ironed out smooth with a hot iron and then trimmed. Mix a little gum-arabic in hot water, so as to make a rather thick mucilage. Place the picture on the page in position and mark just inside the corners. Remove the picture and take some of the mucilage on a ruling pen and draw a heavy line of mucilage from one point to another, so as to make a line of mucilage all around the place where the picture is to be. As soon as the mucilage is sticky, put the picture in place, and a book over it to keep it flat. When dry, you will have a smooth mount that will not curl.

WEIGHT OF MATERIALS.—According to an American exchange, roof boards weigh about three pounds per superficial foot. Terra-cotta tiling weighs from 25 to 35 pounds per square foot. Hollow tile for five-inch partition weighs from 22 to 25 pounds per superficial foot. Lath and plastering, two-coat work, weighs from 9 to 12 pounds per superficial foot. The weight of a superficial foot of brick work, eight inches thick, including mortar, is from 83 to 87 pounds. An iron roof 100 feet wide, with a rise of one-third pitch, will weigh from 10 to 15 pounds per superficial foot.— One hundred pounds per square foot, distributed uniformly over a surface of a bridge, is a safe working standard. The weight per square foot of roof tiling, set in iron or between wood rafters ready for slating is about 12 lbs. A-fireproof floor, constructed of iron beams and four-inch brick arches, will weigh from 65 to 75 pounds per superficial foot. The safe and proper bearing of a joist, timber and girders supporting a floor should not exceed ten tons on brick walls and fourteen tons on good stone walls. A fireproof floor constructed of iron beams and of iron arches made of No. 18 iron, and filled in on top with concrete or slag and cement, will weigh about the same as brick work four inches thick. Fireproof floor made the same as above, with the introduction of hollow tile arches, instead of brick, concrete or slag, will weigh from 12 to 55 pounds, according to the thickness of the arch, running from 4 to 16 inches.

LEAKAGE OF AIR.—The porosity of walls and the vast amount of leakage around door and window frames are seldom appreciated, says Carpentry and Building, by those who talk of stagnant air. Experiments with ordinary windows have made evident a leakage of eight cubic feet per minute while the passage of air through apparently tight walls has been frequently shown by experiment. In one instance a room supplied with hot air from an ordinary hot air furnace was tightly closed. The fire place was stopped up, windows were packed with rubber molding and the door shut. The wood work was sheltered and the brick work oiled. A measurement of the air volume entering showed that it was nearly equal to that when the doors were open. If the air entered it was obvious that it must escape somewhere. A second experiment was made after five coats of paint had been put on the walls and ceiling and three coats on the floor. Still the air entered through the register in large quantities, in fact its volume was only 20 per cent. less than in the former case. Such wholesale leakage readily explains the cause of low temperatures in exposed rooms on windy days, for the outside pressure exceeds that within and the cold air actually leaks through the walls. Surprise is sometimes expressed that in many instances no vent flues are provided when the blower system is installed. This is particularly true of manufactories, offices and stores. Nevertheless, a volume of air sufficient to change the entire cubic contents once in 10 to 12 minutes is frequently supplied in such buildings and escapes only through walls and crevices.

PRESSURE OF ARCH STONES.—The result of investigations on the pressure of arch-stones on a center is, says the National Builder, that the center should be combined in such a manner as to withstand as advantageously as possible the effort of the stones to slide upon their beds. Experiment has shown that hard stones have not any tendency to slide on the bed until it is elevated to about 36°; and it has also shown that when the stone is set in fresh mortar it does not begin to slide until the bed is elevated to an angle of from 34° to 36°. Voussoirs of soft stone, absorbent of moisture, have been raised to an angle of 45° without sliding, when the center of gravity did not fall without their base. Reasoning from these experiments, and assuming 32° as the limiting angle of resistance, the conclusion would be arrived at that the center did not require to commence until the arch stones had reached that angle; and in the Pont du Gard, and the arch of Cestius at Rome, the corbels on which the centers were supported remain at from 25° to 28° above the springing. Beyond 32° the weight on the center goes on increasing as it approaches the keystone; but in practice it is safe to consider the whole weight of the stone as resting on the center, when a vertical line drawn through its center of gravity falls without the lower bed of the stone; and the amount of error is not great, and is on the safe side, if this is taken to be the case when the bed of stone exceeds 60°. But to make this observation more accurate, we quote Mr. Tredgold's words. He says: "When the depth of the arch stone is nearly double its thickness, the whole of its weight may be considered to rest upon the center, at the joint which makes an angle of about 60° with the horizon. If the length be less than twice the thickness, it may be considered to rest wholly upon the center when the angle is below 60°, and if the length exceed twice the thickness the angle will be considerably above 60° before the whole weight will press on the center.

CANADIAN ARCHITECT AND BUILDER.

VOL. VII.—NO. 3. MARCH, 1894 PRICE 20 CENTS $2.00 PER YEAR.

—THE—
CANADIAN ARCHITECT AND BUILDER,
A Monthly Journal of Modern Constructive Methods,
(With a Weekly Intermediate Edition—The CANADIAN CONTRACT RECORD),
PUBLISHED ON THE THIRD THURSDAY IN EACH MONTH IN THE INTEREST OF
ARCHITECTS, CIVIL AND SANITARY ENGINEERS, PLUMBERS, DECORATORS, BUILDERS, CONTRACTORS, AND MANUFACTURERS OF AND DEALERS IN BUILDING MATERIALS AND APPLIANCES.
C. H. MORTIMER, Publisher,
Confederation Life Building, - TORONTO, CANADA.
Telephone 2362.
64 TEMPLE BUILDING, - MONTREAL.
Bell Telephone 2299.

SUBSCRIPTIONS.
The CANADIAN ARCHITECT AND BUILDER will be mailed to any address in Canada or the United States for $2.00 per year. The price to subscribers in foreign countries, is $2.50. Subscriptions are payable in advance. The paper will be discontinued at expiration of term paid for, if so stipulated by the subscriber; but where no such understanding exists, will be continued until instructions to discontinue are received and all arrearages paid.

ADVERTISEMENTS.
Prices for advertisements sent promptly on application. Orders for advertisements should reach the office of publication not later than the 12th day of the month, and changes of advertisements not later than the 5th day of the month.

EDITOR'S ANNOUNCEMENTS.
Contributions of technical value to the persons in whose interests this journal is published, are cordially invited. Subscribers are also requested to forward newspaper clippings or written items of interest from their respective localities.

Subscribers who may change their address should give prompt notice of same. In doing so, give both old and new address. Notify the publisher of any irregularity in delivery of paper.

THE Royal Institute of British Architects have decided that women may take part in the Institute examinations, and the proposal to admit them to membership in the Architectural Association is at present the subject of a lively discussion in the pages of the official organ of that body.

THE Commissioner of Customs states that notwithstanding a protective duty of 50 per cent., large quantities of wire goods and slate are exported from the United States to Australia, and and he sees no reason why manufacturers of these goods in Canada should not compete with the Americans for the Australian trade.

SOME particulars have reached us of the invention by a Canadian of a process which promises to revolutionize the present methods of clay working in connection with the manufacture of brick, terra cotta, drain pipe, etc. It is stated that by this process the time required for the manufacture of materials of this description will be reduced in a wonderful degree with a somewhat proportionate reduction in cost of production. As the inventor has not yet secured the protection of his discovery by letters patent, it would not be just to him that we should make public at present any further particulars concerning it, but we hope to be in a position to do so at an early date.

IN the annual report of the Secretary of the National Association of Builders, presented at the annual convention of that body held recently in Boston, it is made to appear that there are upwards of 40 Builders' Exchanges in the Dominion of Canada, and in affiliation with the National Association. We have no hesitation in declaring this statement to be totally incorrect. There are not a dozen Builders' Exchanges or Associations in Canada, and not half a dozen in affiliation with the American Association. We would be pleased to see the builders of Canada as well organized as the report of the Secretary of the National Association would imply them to be.

A BILL has been introduced in the Ontario Legislature which provides for the taxing of church buildings. Petitions have also been addressed to the Legislature by the City of Hamilton and other municipalities praying for the enactment of legislation with this object. The passing of such a law would doubtless affect very materially the cost of many church buildings erected in the future, a result which would scarcely be appreciated by architects, whose commissions are usually based on the cost of the building. It would have a good effect, however, in the direction of restraining church trustees and committees from vieing with each other as at present in the erection of expensive churches, the funds for which must in most intances be raised by heavy mortgages.

MR. WAITE, of Buffalo, the architect of the new Legislative buildings at Toronto, is said to have recently preferred a claim for commission, amounting to about $28,000 in addition to the $38,000 or more which has already been paid to him by the Government. It will be remembered that the original limit of cost of the buildings was $750,000, and that notwithstanding the designs submitted by Canadian architects were thrown out because the tenders on them exceeded this amount, Mr. Waite was afterwards given the work and allowed to expend nearly a million and a half upon it. It is said that the understanding was that he was to be paid a commission of 5 per cent. on the original estimated cost. However this may have been, he now demands his commission on the full cost of the building.

An American contemporary says: "We have had so many applications of late for sample copies of The Southern Architect, which are unaccompanied by the stamps or other evidences of a disposition to appreciate the favor of such an accommodation, that we have been compelled to refuse all such requests. In fact the calls for samples are so numerous and regular that we suspect the sample copy fiend is trying our good nature and attempting to save the two dollars necessary to insure the regular monthly arrival of the paper." We have had a similar experience, and have satisfied ourselves that there are in the United States a large number of builders and some persons claiming to be architects who make a practice of writing to the publishers of architectural journals for free sample copies, with no intention of becoming subscribers. By this means they secure a collection of valuable illustrations and printed information at the cost of a few cents for post cards. From one individual we received at different times no less than three requests for sample copies, which confirmed our previous suspicion that a fraud was being practiced. Since then requests for free sample copies have been met with refusal unless they were accompanied by some evidence of the bona fides of the applicant. Publishers of architectural journals should refuse to be further victimized.

Since the ejectment by the architect of Mr. Neelon, the contractor for the new city buildings at Toronto, and the granting by the Courts of permission to the architect to proceed with the erection of the building, both parties to the dispute have been busily engaged in collecting evidence with which to substantiate their positions when Mr. Neelon's suit for damages should come up for hearing. The case, which was looked forward to with much interest owing to its novel character and the magnitude of the interests involved, came up for argument before Mr. Justice Rose at Toronto in the early part of the present month. From the number of the witnesses and the mass of evidence ready to be submitted, it appeared probable that the case would occupy several weeks, but circumstances arose which brought it to a close for the present on the fourth day, when but little evidence had been adduced. Mr. Blake, the plaintiff's counsel, raised the contention that Mr. Lennox, the architect, had not the power to dismiss the contractor without the written consent of the Court House Committee of the City Council. The proceedings were adjourned to allow the Judge to consider the point, and as a result of such consideration he decided on the following day that the architect had the power under the contract to dismiss the contractor. Mr. Neelon's counsel having stated that his client was averse to proceeding further with the evidence in this Court, Mr. Justice Rose dismissed the action, with costs against the plaintiff. The case will be appealed to the Chancery Divisional Court, and should the decision there prove unsatisfactory, the plaintiffs will doubtless carry it to the highest court of appeal.

We have heard much during the last month of the sufferings of the unemployed, and the unusual extent to which lack of employment prevails. We have witnessed also the unusual sights of the principal thoroughfares of Toronto being blockaded at certain hours of the day by crowds of people waiting to have food and clothing dispensed to them by certain of the newspapers, which, judging by the manner in which their charity was heralded, were quite as anxious to attract attention to themselves as to relieve the needs of their fellow citizens. We believe that positive injury has resulted from the methods pursued by these papers. In the opinion of ministers of the leading churches and of persons connected with the numerous charitable organizations of the city, the distress existing this winter is but little greater than in former years, yet it has gone abroad to the world that our streets are thronged with people clamoring for bread, while the overdrawn pictures of want which have appeared in the newspapers have emboldened the idle and dissolute classes of the community to assume a threatening attitude. The suggestion has very properly been made, that instead of paying out large sums of money to the unemployed for snow cleaning, and such like unnecessary work, the City Council should endeavor to provide useful employment by carrying out the construction of some of the needed improvements which must be undertaken in the near future, as for example, the trunk sewer or the water tunnel recommended by the City Engineer. If such works as these are undertaken largely with the object of relieving the wants of the unemployed, it should be with the understanding that the unions will not as in the past insist on the city paying a rate of wages equal to that which might be expected under more prosperous conditions.

The City of Toronto is once more giving evidence of its conservatism in adhering to village practices, by attacking its officials, and especially its engineering department. The present engineer has shown immense capacity for organization and grasp of the details of the whole work of his department, to which was added the charge of the water works, with its unenviable legacy of a leaking conduit, broken connections at all points, leaky pumping wells at the pump house and numerous other troubles. The work of the city has never been carried on so smoothly and satisfactorily, and instead of being thankful for their lot, a few new aldermen have assailed the whole organization of the civic staff. Of the miserly savings effected in the engineer's department,—about $3,300,—over $2,000 is contributed by four officials. With a most excellent and unlimited supply of pure water at their door, an unreasonable agitation has been sprung on the Council to bring water from Lake Simcoe. The council cannot be induced to consider the report of their own engineer which they themselves ordered him to prepare; it is at present waste paper. Lake Simcoe is the hobby of one man who seems to have completely hypnotized a section of the Council into believing and desiring to see carried into effect a scheme which will be the ruin of those who undertake it. Ten thousand horse power from Lake Simcoe to begin with, and any amount afterwards, to give power, light and heat to poor languishing Toronto, is as glibly talked about as building a head race for a flour mill. Millions of dollars of expenditure are spoken of with such levity that one is induced to believe the whole financial world is longing to help Toronto to drain Lake Simcoe, leave its 10,000 H. P. higher and drier than Noah's Ark, and seek no return or revenue for the monies invested. It makes one tired to hear this constant agitation about Lake Simcoe water. The promoters appear to have a considerable following in the Council; let them get their friends to move for an appropriation to extend and complete the surveys made when Mr. McAlpine and Messrs. Hering and Gray were here. An expenditure of $5,000 will effect this, prepare estimates, and give the Toronto public full and reliable figures on which they can discuss intelligently the question of this source of water supply, and it will effectually settle the water supply, power, heating, aqueduct and canal schemes.

The citizens of Toronto should feel indebted to Colonel Sweny for having suggested in the public press the construction of waterways on Toronto Island, which should afford communication between the different parts of the island by means of steam or electric launches, in preference to electric railway transit. Undoubtedly it would be possible by such means as Colonel Sweny has suggested, to make of the island a most attractive and healthful resort. In detail his various suggestions appear to be in some respects inconsistent. He objects to the electric cars because, as he states, they would create noise and by conveying crowds from one Coney Island show to another, the whole place would be given up to revelry and clamor. On the other hand he suggests the making of a race course, which would become the champion course of Canada and attract thousands of visitors annually to witness the great races of professionals and amateurs. The carrying out of this suggestion would probably destroy quite as effectually as the electric cars the character of the island as "a quiet and delightful retreat where many a family flying from the city's heat may find rest in the summer days." With the scheme as a whole, however, we are in entire accord. The World's Fair grounds at Chicago were a sufficient indication of what might be done at Toronto. We cannot agree with Colonel Sweny's statement, that "the past history of the island conclusively proves that neither the people nor its representatives are alive to the importance of the property they own." This was true as regards the island a few years ago, but the Parks and Gardens Committee of the City Council have within the last five years changed the aspect of the central portion of the island in a manner which has very materially increased its attractiveness,

and by doing so have shown themselves to be alive to the possibilities of improvement. The Toronto Architectural Guild at its last meeting discussed this subject, and unanimously adopted the following resolution, which will be forwarded to the City Council: Moved by E. Burke, seconded by S. H. Townsend:—"That the Architectural Guild respectfully urges upon the City Council the wisdom of a very careful consideration of the transportation and other problems at the island; that we deprecate the proposed introduction of the noisy and dangerous trolley, and would advocate such a scheme as that outlined by Col. Sweny in the public prints. The artistic effects in the way of connected lagoons and wooded islands, such as were introduced at the Chicago World's Fair, are possible here on an extended scale, and we think this generation will be very remiss and lacking in breadth of view if such magnificent opportunities are not taken advantage of from the beginning. The sanitary advantage gained will also be of immense benefit. We beg to suggest a very careful consideration of the whole subject and the engagement of the best available landscape architect to advise and plan for what may be made in time a Toronto Venice".

AN INTERNATIONAL EXPOSITION AT TORONTO.

As this number of the Architect and Builder goes to press, our attention is called to a resolution adopted by the Toronto Board of Trade, favoring the holding of an International Exposition at Toronto a couple of years hence, and to an editorial article in the Toronto Globe in support of the project.

The space at our disposal will only permit us briefly to express the hope that immediate steps will be taken to carry out the undertaking. It would be the grandest possible advertisement for Canada, and would be the means we believe of giving a much needed impetus to immigration and business enterprise, while needed employment would be furnished to the laboring and artizan classes. The conditions are likewise most favorable to the carrying out of the scheme at the smallest possible expense. Architects and builders, who, with other classes, would be benefitted, should give the enterprise their prompt and earnest support.

TORONTO BUILDERS' EXCHANGE.

Toronto, March 6th, 1894.

Editor Canadian Architect and Builder.

Sir,—As a member of the Supply Dealers Section of the Toronto Builders' Exchange, I have to complain of the treatment which I have received at the hands of some of my fellow members. It is one of the regulations of the Exchange that members belonging to the Builders' Section who may purchase materials from members of the Dealers' Section, shall receive a certain discount off prices charged to outside builders on condition that the materials thus purchased are paid for within 30 days. Many of my fellow members to whom I have sold materials, allowing them the cash discount with the understanding that the goods would be paid for within the specified time, have failed to make payment for two, three or four months, and have then insisted on getting the benefit of the discount, notwithstanding their disregard of the terms upon which it was to be allowed, and unless their demand is complied with, I am given to understand that they will withdraw their orders from me. In view of the dull times, they well know that every dealer must be anxious to avoid loss of trade, so take advantage of this fact to repudiate the well known conditions of purchase as laid down by the Exchange.

This is a matter which the Board of Directors of the Exchange would do well to take cognizance of, as unless the members of the organization are compelled to deal fairly by one another, the benefits of membership must soon disappear.

Very truly yours,

Material Man.

PERSONAL.

Mr. P. Lacroix, of Montreal, was a delegate at the convention of the National Association of Commissioners and Inspectors of Buildings recently held in Boston.

The death is announced at London, Ont., of Mr. William Wales, father of the wife of the Mayor of that city. Mr. Wales, who was a native of Devonshire, Eng., was a well-known contractor, having carried on business in this line at Kingston, Ont., and having recently been engaged on the construction of the Parliament Buildings in Toronto. The deceased was in his seventy-sixth year.

Much surprise was occasioned a few days ago by the announcement that Hon. C. F. Fraser, who has occupied the office of Minister of Public Works in the Ontario Government since 1874, had tendered his resignation. Mr. Fraser has been in ill health for several years past, and on more than one occasion would have resigned his duties had not his colleagues in the Ministry prevailed upon him to continue in the position.

TORONTO TECHNICAL SCHOOL.

There can be but one idea with reference to the usefulness of technical schools, and we believe that the majority of the people in civilized countries hold to that idea, namely, that when managed by competent bodies of men forming the board of management, with zealous instructors, duly qualified, under them, nothing could be of greater advantage to the mechanic, anxious to obtain an education in his particular trade, which he could not possibly obtain without them. When, in addition to the facts that a technical school exists in any city, and is well governed and managed, the instruction is given absolutely *free*, the boon to the working man is simply immense. That a man should be able to acquire not only an insight into, but a thorough training in the science of his trade by diligent attendance three or four nights a week in a well lighted and well ventilated building, listening to the instruction given in a manner suited to his ability to grasp it, must be regarded as a very valuable privilege, and men who will not take advantage of all this, must be considered drones of their class. But everything in the success of such an institution must depend upon the zeal of the board of management, and the ability of the instructors. The board of management must be composed of men who are to a greater or less degree experts in the branches they represent; they must be men who will throw themselves into the work of the institution with zeal and unflagging interest, who will carefully watch their several departments and see that those who come up for instruction are receiving all that the school is able to give. Under them must be a supervisor or head master, who is responsible for the direct management of the school, and while capable of taking occasional classes himself, must be able to know that all the other classes are well managed, that the teachers are doing a thorough work and are able to impart instruction.

The teaching staff must not only be persons who have passed qualifying examinations and are experts in their particular lines, but they must have the *faculty of teaching*, which is by no means possessed by every one who may be considered an expert in any particular science. Necessarily, of course, they must have a love for teaching, and the ability to guage the minds of those who come to them for instruction, and be readily able to grasp the meaning of the duller students who have difficulty in expressing their needs succinctly. Patience is a gift that must be possessed by all teachers, and then with a love of the subject and a desire to infuse into the students an equal love of the subject, the qualified expert will be a successful instructor.

We have in Toronto a technical school the general working of which is little known to the public. It is in its infancy, and much that such an institution desires to accomplish, is necessarily beyond the means in hand at present. But it speaks well for the school that the attendance has already become too large for the rooms now occupied, and the work done by the students such as is of a character that can be exhibited, is very creditable to the institution.

The Toronto Technical School has a board of management composed of the Mayor of the city, the chairman of the Executive Committee and three aldermen, ex officio members; two experts in technical education; two stationary engineers; two members of the Council of the Ontario Association of Architects; one manufacturer, and five representatives of the Trades and Labor Council. Of the technical staff, the head master Mr. Duff, and one other, are B. A's, and graduates of the School of Practical Science; one other is a graduate of the same school; one is a B. A., another a B. A. and M. C., while another is a member of the Ontario Association of Architects, and another a lady, is a B. A., and holds the position of Public Analyst.

We have given these particulars because of our insistance upon the necessity of proper qualification in the instructors of a school such as the one in question. It may be said that something of the same importance must attach to teachers in all schools, but there is even a greater necessity in an institution of this kind because it is not rudimentary work that is here studied, but work that cannot be successfully carried out but by eminently qualified teachers. Mechanics, chemistry, physics, mathematics, descriptive geometry and drawing cover a wide range of technical study, both theoretical and practical, starting at a point considerably in advance of the highest grade of public school instruction and stretching forward to an indefinite grade of study in science. One of the important points for first consideration therefore must be: what shall be the highest limit of the instruction given in a particular school. This must be decided by two things: first the amount of funds at disposal for the purchase of apparatus and appliances, and secondly by the requirements of the majority of the students likely to attend. There must be some limit, or the theorist might carry on his course over several years and a great deal of time would be spent in mere speculation, while in practical matters it would be a mistake to go beyond the recognized requirements of particular trades. It has been found necessary to treat in an elementary manner upon some subjects, such for instance as arithmetic and mensuration. A student would profit little by the most excellent instruction in mathematics unless he had a certain fluency in arithmetic, and as most students coming first to the school, have passed some years since they left the public school, their arithmetic, except in very simple matters, must necessarily be "rusty" even if they ever learned enough "at school" to enable them to take up the higher branches. Descriptive

geometry and drawing cover, perhaps, a larger field than any other subjects, from practical geometry, drawings of constructions in all trades, the setting out of carpenter and joiners' work (some of which is necessarily indicated), drawings for pattern makers for machinery, up to free hand, ornament and design, and even architecture. Thus this subject illustrates, in a way, the importance of a thoroughly qualified instructor.

Another very important point to which a Board of Management must be thoroughly alive is, that having satisfied themselves with the *qualifications* of the teaching staff, they ascertain from time to time that the teachers are making progress themselves and keeping abreast of the times. It is very easy for an instructor in any subject to "get into a groove" or even to become careless in the preparation of his lectures; the problems he propounds must be progressive and must carry with them important lessons; and again these problems must be suited to the various stages at which the students have arrived. A problem may be in every respect a very excellent one, but if it goes beyond the instruction given, or does not come up to it, it is valueless, for in the one case the student will work it out with the greatest ease as belonging to a stage he has passed, or in the other, it will be a waste of time for him to puzzle over something about which he has not as yet received full instruction. It has been said that the guarantee against failure, in this respect, on the part of the instructor would be, that the students would themselves complain that they did not obtain that which they found of necessity to them. But it must be remembered that the majority of students, probably, would not have sufficient ability to detect any weakness of this kind in the teacher, and few would like to take upon themselves the responsibility and the great unpleasantness of making a complaint. The consequence would be, that one or two, who felt this, but did not see how to help themselves would leave, while the majority would remain and waste their time under the impression that they were progressing. Examinations of students to ascertain their progress would not mend matters or be a sufficient guarantee in the matter. This work of keeping the instructors up to the mark would, we suppose, devolve upon the two experts in technical education. These two experts are Prof. Galbraith and Dr. R. B. Orr, and we find their names head the list of the "School Management Committee." In these two gentlemen we think the public have a thoroughly satisfactory guarantee in this particular.

One point which concerns the public generally more perhaps than any other, and vitally concerns the institution itself, is the salaries paid to the instructors. The suggestion of reduction of question of salaries is now occupying the attention of the Board of Management. Every institution in its infancy, to be a success, must be carried on on the most economical principles consistent with the objects to be attained. An institution of the kind in question requires a large number of appliances for the execution of its work, as well as competent instructors, and the instructors must necessarily be hampered in their work without a sufficiency of appliances. When the appropriation for the work of the school is limited, it becomes a nice question as to what proportion shall be spent in salaries and what in the purchase of appliances, having first deducted from the appropriation the current expenses, such as rent, fuel, light, etc., etc. It seems to us that the subject has not received the attention it deserves at the hands of the board of management, and that the principle in force in the technical school of Toronto is an easy one of disposing of a difficult question, but that it is open to question as to whether it is very fair to the instructors themselves or altogether judicious in view of the limit of the appropriation. We do not for a moment agree with undervaluing the services of qualified teachers, but the point is one of utilizing the funds to the utmost advantage. Out of an appropriation of $7000, $4000 is divided equally among the eight instructors, no difference being made between one who has to spend a large amount of time in necessary preparation of his lectures and one whose subject being practically book work, does not need much time for preparation—between one whose subject is endlessly progressive, and one whose subject is by very nature, a limited science. In the first place $500 seems a large sum for an instructor who having the whole day for earning his livelihood, puts in say three nights a week for about six months of the year, and has little or no preparation to make for his class work at the school. But it does not seem too much for one who has to put in five nights a week for the same time, and has to spend two or three hours a day besides in preparation, even if he is an expert, and thoroughly posted on his subject.

In this institution the principle is that the work of instruction is to be divided up as equally as possible among the eight instructors, and if one has more than he can do in one subject, he must get the assistance of one whose time is not so fully occupied, so that the time of each shall be equally employed and all receive the same remuneration. But is there not a weakness here? The expert in one science is not likely to be an expert in another. If the instructor in drawing had too much on his hands, he could hardly obtain assistance from the expert in chemistry, or the expert in chemistry from the teacher of mathematics. While we do not advocate the reduction of salaries as an all round principle, nolens volens, we think that there would be a decided gain to the institution if the matter were regulated in a rather more practical manner than at present.

The limited space at command of the institution should make the matter of admission to its benefits, one of some consideration. At present any applicant (unless something serious is known against his character for instance) is admitted. A youth may think it will do him good to attend certain classes and he applies for admission; he attends a few nights and "drops out"; another may find it a pleasant way of spending a few evenings a week, taking up much valuable time of the instructor, and learning nothing, or one may come to learn, for example freehand drawing, not for the purpose of improving himself at his trade, but simply as an accomplishment. Thus, the space being limited, these three would shut out others, worthy seekers after knowledge as a means of improvement in their trades, for whom we conclude the institution is primarily intended. Now that the two dollar deposit, originally demanded from an applicant is not required, there is absolutely no guarantee of serious intention on the part of the applicant. Some kind of enquiry should, we think, be made concerning the applicant before admission is granted, of a fuller scope than is supplied by the simple form of application.

There is one other point upon which we wish to touch, that is examinations. The institution, like all others in their youth, cannot be expected to produce in the short time that it has been at work, very great results, and the public should not be disappointed that experts are not turned out at the close of every term. The work is necessarily progressive, and a certain course must be taken (in some classes of two years duration), before the ground is covered. There are certain disadvantages perhaps in permitting each instructor to examine his own class, but there are many advantages, and on the whole this principle really has proved in the majority of institutions to be more satisfactory than the employment of "outside" examiners. The "outside" examiner is generally or should be necessarily an expert among experts, but he has no intimate knowledge of the students he has to examine. Consequently he looks over the work through which the students have waded in the term, concludes that they have reached a certain standard, and he possesses certain or if we may say so, stock or test questions, which, if every student was of the same mental calibre as his neighbor, would no doubt test their abilities very well. But in all classes, there are some students brighter than others, and some who cannot by any means grasp a subject so easily as others. Moreover every examiner knows that many a student fairly well posted in his subject and who has shown great diligence at his work may fail completely at an examination through nervousness or the inability to comprehend the exact meaning of the questioner; while it may happen and has happened that a student may be acquainted with the peculiarities of a particular examiner and come out with flying colours at an examination who really was not so well grounded as the former example. There is a difficulty here that is not easy to get over in the way of satisfying the public that the results of the work are commensurate with the appropriation. A certain amount of result may in some branches be seen, as for instance in the exhibition of drawings executed by students, but even this is not satisfactory, for if a student exhibits a beautiful drawing of an elaborate machine, the public cannot know from the drawing that the student has an accurate knowledge of the use and working of every portion of the machine. A knowledge of algebra and such sciences cannot be exhibited, nor can the result of a two years course of chemistry be practically demonstrated to the public mind. In this matter the public must trust to its representatives on the board of management. The duty of the public to themselves is to see that the best men for the positions are elected to fill these offices and the public may and should scrutinize carefully the work done and the attention given by each member of the board.

A visit to the institution satisfies us that so far as it is able to go, the lines upon which its work is based are very excellent. It is a school worthy of a much larger appropriation, but the foregoing suggestions with reference to improvement in management present themselves, and are worthy we think of investigation.

Our thanks are due to the very courteous reception we met with at the hands of Mr. Duff, and the pains he took to give us the fullest information concerning this valuable institution.

ONTARIO ASSOCIATION OF ARCHITECTS.

THE first of a series of public lectures to be delivered under the auspices of the Association was given by Mr. Grant Helliwell, in the School of Practical Science, Toronto, on the evening of Thursday, the 8th inst. The subject of the lecture was "Current Architectural Styles." The subject was treated in a most interesting manner, and illustrated by a stereoptican under the direction of Mr. C. H. C. Wright, Lecturer in Architecture in the School of Science.

In substance the lecture is embodied in the paper read by Mr. Helliwell at the recent convention of the Association, and printed in the present number of this journal. It was, however, considerably amplified and popularized as befitted the occasion.

The audience numbered between two and three hundred, but strangely enough the students and to some extent the architects also were conspicuous by their absence.

It is learned that a special autumn meeting of the Association has been decided upon. It will probably be held in September. It will not be a business meeting, but a meeting for instruction, for which an interesting programme of papers, etc., is to be provided.

ROCKS. *

Geologists and architects have at least one interest in common, they both deal in what a geologist calls "rocks" and an architect "stone." The rocks of the geologist include, however, the sand of a seashore, the soil of a field and the ice of a glacier, whereas no architect would think of building in any of these materials unless perhaps an ice palace at Quebec this or some other winter. The geologist when dealing with rocks is apt to dub himself a petrographer or a lithologist, but the architect is more modest and gives himself no special name because he builds in stone.

The petrographer divides rocks into three grand divisions,—massive or igneous rocks, resulting from the cooling of melted material; schistose rocks having their minerals arranged in a parallel way so as to split most readily in one direction; and sedimentary or clastic rocks made of fragments of other rocks deposited by water. The massive rocks show the greatest variety of minerals, and are always taken up first. Their mineral constituents are of two kinds—essential, when their absence would throw the rock into another species, and accessory when less important.

The mineral playing the largest part in the formation of rocks is quartz, rock crystal when it displays its own form, a six sided prism ending in a pyramid. It is the hardest of the essential rock-forming minerals, is almost unattacked by the weather, and therefore is the most useful constituent of many stones suitable for building. Next in importance come the felspars, orthoclase with its flesh red or white cleavage surfaces, and plagioclase showing delicate striations, on cleavage planes. The former is a silicate of alumina and potash, and the latter of alumina and soda or lime. Some of the plagioclase felspars have a magnificent play of color as in labradorite. Of the darker rock minerals, mica, hornblende and augite are most important.

There are several kinds of mica, but we need mention only muscovite, a silicate of potash having pale colors, and biotite, a magnesian silicate very dark in color. All micas may be recognized by their very perfect cleavage into exceedingly thin elastic plates. Hornblende is a dark colored silicate having two planes of cleavage with an angle of 124 degrees between them. The scales cleft off are not elastic. Augite or pyroxene, another dark, almost black, silicate, has usually no distinct cleavage, and may be distinguished thus from hornblende. Of the accessory minerals, few are of much interest to us, though garnet, often of a fine red color, occurs in many rocks around Toronto, and tourmaline in black triangular prisms may sometimes be seen. The most important of the accessory minerals to the architect, is iron pyrites, a hard, brassy looking sulphide of iron crystallizing in cubes, which under the action of the weather may change to a sulphate and finally stain the rock where it occurs rusty brown with oxide of iron.

Turning now to the rocks themselves, granite is naturally taken up first by both petrographers and architects, as the most widespread and useful of the group. It consists essentially of quartz, felspar and mica or hornblende, and takes on grey or flesh red colors from the prevalent orthoclase felspar. It is one of the handsomest and most durable of building stones and but for its great hardness would no doubt come into much wider use. Its one defect is the ease with which it crumples under the action of intense heat, as shown at the Boston fire. If quartz be omitted from granite the rock is called syenite, which has the same colours and uses as the previous rock, though a little softer to work. When the felspar is striated and mixed with hornblende, forming a dark green or black rock, it is named diorite; if augite is the dark mineral the rock is diabase or gabbro. All these rocks fall into the same line in the hands of the builder, who sometimes calls them black granite.

Porphyries are rocks, unlike those that have been described, in that the general mass is fine grained or compact in structure enclosing larger grains or crystals of quartz or the felspars. Some of the porphyries are very handsome stones for ornamental work, but are little used in building.

The more important ancient massive rocks have now been described; and it will scarcely be necessary to take up in detail the corresponding series of modern eruptive rocks, including the lavas, such as trachyte and basalt; since this whole group is absent from eastern Canada.

The schistose rocks, too, need only a brief mention, since only one of them, gneiss, practically granite, having a parallel arrangement of its mica plates, is used to any extent for building. In Norway one sometimes sees a whole house built of gneiss, roof as well as walls. Far more important are the fragmental or sedimentary rocks, which provide the most commonly used building stones. We may divide them into three groups, those made of clay in some form, those made up of silica or the silicates (quartz, felspar, etc), and those which consist of carbonate of lime or of this with carbonate of magnesia.

The clayey or argillaceous rocks are usually too feeble and easily acted on by the weather to be of use in building. The slates, however, which are clays consolidated and metamorphosed, are an exception, since innumerable minute crystals of mica and other minerals have begun to form in them binding the materials together and giving a resistance to the weather surpassed by no other rock. The perfect cleavage which gives slate its value as a roofing material does not correspond to the stratification, as one would expect, but has been caused probably by strong lateral pressure in mountain building. The different tones of color in slates are taken advantage of by architects to give variety in roof effects.

Perhaps the most useful group of rocks in architecture is that of the sandstones. Breccias, made up of large angular fragments are too rare to find much place as a building material; and conglomerates, formed of rounded pebbles cemented together, are also rarely put to use, though some notable buildings, such as the Pitti Palace, are built of them. Our brilliant jasper conglomerate from Lake Huron with its red pebbles in a white ground might give striking effects, though it would be very hard to work. It would probably last for eternity, however, if put into a building. Sandstones, on the other hand, are among the most favored building materials. They consist chiefly of grains of quartz, often with a large admixture of fragments of felspar or other silicates, and result from the destruction of the older massive rocks. The cement binding the particles together has a great effect on the durability of the stone and should receive more attention than it does from architects. A siliceous cement forms a rock difficult to work but that will practically last forever. A ferruginous cement consisting of oxides or carbonate of iron is a durable one and occurs in many reddish or brownish sandstones. The cement is said to be calcareous when carbonate of lime is deposited between the sand grains. Such sandstones effervesce with cold, dilute acid, and the lime is more or less easily attacked by rain charged with carbonic acid from the air of cities, allowing the stone to crumble. The least efficient cement of all is argillaceous or clayey, and sandstones containing it readily disintegrate when exposed to the weather in a climate like ours. The clayey odor when breathed upon affords a rough test for the argillaceous cement. It is an unhappy fact that the durability of a sandstone is often in inverse ratio to the ease with which it is worked, so that the builder is tempted to use the poorer qualities.

Last come the carbonates, consisting of calcium carbonate in limestone, and of calcium and magnesium carbonates in dolomite. The two may be distinguished by the action of cold acid, which effervesces strongly with the carbonate of lime, but hardly at all with dolomite. The limestones are generally formed of broken shells, though in many compact varieties, such as lithographic stone, the fossils have completely disappeared. Porous modern limestones, formed by springs are called travertine. The most ancient limestones have been so metamorphosed as to become thoroughly crystalline, and when very fine grained and pure white are statuary marbles. Many of the colored varieties of so called marble are really, however, uncrystalline limestones. The limestones are often admirable building stones, durable and handsome, but are apt to be attacked by the atmosphere of great cities charged with acid fumes. The dolomites resist this action somewhat better. A very handsome variety of chemically deposited carbonate of lime, sometimes used for interior decoration, is called Mexican onyx in the trade, though incorrectly, since the true onyx is a variety of silica.

The coloring matter of rocks is usually some compound of iron. Reds are caused by the sesquioxide, hematite; browns and yellows by the hydrous or brown oxide. Red and brown sandstones are good examples of this, the paler they are the less oxide of iron they contain, while pure white ones are practically free from this metal. The flesh color of orthoclase felspar in the granites arises also from the red oxide of iron. On the other hand silicates and other compounds of iron in the monoxide state show various shades of green or gray, or almost black, as in the diorites and other greenstones, in green slates, and greenish grey sandstones. These green monoxide compounds of iron tend to weather into the ruddier sesquioxides. One often notices that pale greenish sandstones turn yellowish or brownish on exposure, a result of slow oxidation of ferrous oxide. The darker limestones are usually colored with bituminous or coaly matter, which on exposure gradually oxides; so that a blue limestone, like that of Kingston, eventually bleaches to a pale grey, almost white; Kingston by moonlight seems built of marble.

The weathering quality of rocks is a matter of great interest to architects, for on this turns the permanence of their work. Certain rocks, such as quartz des and sandstones with a siliceous cement are practically indestructible by the weather, as one can see on surfaces scoured by glaciers during the ice age 7000 years ago, but still showing the polish and scratches then given them. Rocks formed of silicates, like granite and syenite, are also very resistant; others like the limestones and marbles are slowly dissolved by rain and are more rapidly acted on by the impure air of large cities, which contains traces of sulphuric acid. The dolomite of the English parliament buildings is said to be suffering badly from this cause. Sandstones with clayey cements are readily disintegrated in moist and changeable climates; and stone containing much iron pyrites should be looked on with suspicion, since it is very apt to weather into brown oxide of iron, weakening the stone and giving rusty stains, as in the parliament buildings at Ottawa. The porosity of a stone is a matter of prime importance in a climate like ours where water soaked walls may be quickly crumbled under the action of frost.

In rocks composed of several different minerals, like granite, great changes of temperature tend toward disintegration through unequal expansion. Quartz has a cubic expansion of .000036 for one degree centrigrade, orthoclase only 17 parts in a million. In case of a great fire where the temperature may be raised suddenly 1000 degrees or more, this unequal expansion sets up strains which splits off the surface, as in the great fires of Boston and Portland, where massive granite buildings crumbled to ruins. One would expect limestones to burn to quicklime and thus fall to pieces, but actually they resist far more heat than granite, while sandstones resist fire best of all.

The last point to be referred to is the best means of testing a rock intended for building purposes. The test of time is of course the most convincing of all, but then one cannot always wait a thousand years to see how durable a building stone is. The resistance of a cube of stone to crushing strain gives useful evidence as to its strength, and the amount of water it absorbs helps to a decision as to its durability in frosty climates; but the most valuable test of a scientific kind is a petrographical examination. The lithologist unlike other men can look through stone walls. By the microscopic study of thin rock sections one can determine the actual minerals that make up a rock, their relationship to one another, their state of freshness or, decay and the character of the cement that binds the particles together. No other method will give such complete evidence as to the internal structure of a rock, on which its durability depends, as a careful examination of sections under the microscope.

* Paper by Prof. A. P. Coleman, of the School of Practical Science, read at the annual convention of the Ontario Association of Architects.

THE ARCHITECT.*

As this is the first time that I have had the pleasure of reading a paper either before architects or others I sincerely trust that you will bear with me, look kindly upon any errors I may make, and if the paper as a whole be weak I hope you will be light in your vituperation and that I may be strengthened in this to better prepare another at some other time. I have chosen as you see for a subject "The Architect."

It has been said that any one possessing the knowledge of a poor carpenter, the skill of an indifferent draughtsman, a little audacity and a ten dollar bill, can appoint himself an architect. Certainly in the present state of affairs all persons are privileged alike in practising architecture, or rather in, shall I say, designing, and superintending the construction of buildings, notwithstanding the important consideration of health and safety of life involved, to say nothing of the hideous aberrations that our cities and towns are often besmeared with by men whose only passport to public patronage is their "gall" and the assumption of the name of architect.

It seems a pity that something cannot be done to limit the practice of architecture to properly qualified men. I have sometimes thought that instead of having the word "Registered" removed from Clause 25 of the Ontario Architects' Act, that those only who have passed examination be allowed to call themselves "Registered"; all others who though still being allowed to practice, would not term themselves "registered architects" and thus save the ignorant public, if they choose, from being victimized.

I have also thought a measure of the trouble might be averted, the beauty of the city improved and the architectural profession edified, if the city would not grant a permit for any building unless a copy of the plan as made by, and bearing the signature of an architect be filed, and if the architect would not undertake to make plans for any person unless he be commissioned to superintend the construction of the building as well.

Loan companies and money lenders would have better security for their money if they would insist that the building on which they are asked to advance money should be planned and superintended by an architect.

But before the general public will be able to distinguish between architects and ARCHITECTS, it will necessary that they be educated to distinguish between good and bad architecture—to accomplish which there is no doubt this Association has done and is doing a great deal, but perhaps if architects would voice their opinions through the press oftener on things architectural the matter would receive more consideration from the public. The taste of the coming generation would be greatly cultivated along this line if the study of architecture were brought into our public schools. In whatever way this great change shall be brought about I cannot say, but I sincerely trust that the time is not far distant when incompetent men, such as real estate agents and mechanics, will not be allowed to practice architecture without the proper qualifications.

How often we see exemplified the sarcasm of Lessing when he says—

> Tomkins forsakes his last and awl
> For literary squabbles,
> Styles himself poet.
> But his trade remains the same—he cobbles.

I remember hearing of one of this stamp erecting a large building for manufacturing purposes where all the internal supports were wooden posts from basement floor to roof; the weight to be imposed on each support would be something enormous. Under each post he had one stone 18" × 18" × 9" resting on the earth, and but for the better judgment of the builder who objected to carrying out the plans in this respect, there would probably have been very disastrous results. This architect, with fear and trembling, went to the owner and made the excuse that owing to the softness of the earth which he had not foreseen, it would be necessary to enlarge the footings under the posts.

When we hear such things as this about people who call themselves architects, we can hardly wonder at owners employing what is known as the "practical man," instead of an architect, for this kind of work.

Plagiarism, or purloining the designs of others and calling them your own, is, unfortunately practiced by this class of people who usurp the name of architect, who, if they do not crib the entire design, pick out the features they think suitable for their purpose from the published work of other architects and who manage in this way to form some sort of a design, and hearing whatever praise the unsuspecting client may have given expression to, he "bears his blushing honors thick upon him" just as if they had been honestly merited. I remember being asked to compete for a small country church. Out of respect for the feelings of the kind friend through whose influence I was asked, I submitted plans, but was not, however, the fortunate man. In conversation with the secretary of the Building Committee he informed me that he had in his possession one design which met with the approval of the committee. He showed me the plans and perspective drawing, the latter being a tracing from the CANADIAN ARCHITECT AND BUILDER of a published design which I myself had made.

Dryden has aptly marked the three steps in the career of most men of genius, thus—

> "What the child admired
> The youth endeavored and the man required."

In my mind I can scarcely conceive of a man being proficient in this profession whose career has not been marked by these three steps—one who has studied the profession from his early youth, spent a number of years in the office of a recognized member of the profession at all kinds of work in connection with architecture, and who makes a constant study of his profession.

It is perhaps a misfortune of the profession that its members must be at once artists, business men and scientific experts, and they cannot choose to be either more than the other without great injury to their usefulness and success. It is thought by a great many to be beyond human capacity to excel in design and anything else at the same time. The man who would be a thorough architect, while taking great pleasure in exercising his designing qualities, should not overlook the importance of making constant efforts to keep himself familiar with details of construction, prices and specifications.

It is often found that an architect for fear of discouraging his client at the beginning, systematically makes all sorts of encouraging responses to enquiries regarding the cost, and does everything to get a building started; so the owner after having seen a most elaborate sketch is tempted to go on with the work, although the tenders have now exceeded his appropriation by say $2,000. Afterwards tenders are to be taken for mantels, gas fixtures, heating, etc. Of course the architect told him that these were not included in the original estimate, but he had no idea they would run into so much money; so that when the building is completed it has cost several thousand dollars more than he intended. The owner in his discouragement of course blames the architect. If the architect had spoken plainly to his client in the first place and told him he was expecting too much for the money, all the trouble would most likely have been prevented. There is far more merit in being able to build well on a minimum allowance than to design artistically, but unfortunately without any regard for cost. What credit is it to the architect who makes a pretty building where cost has not been a consideration?

The architect should bear in mind that his first clients will generally be his personal friends, and that defective specifications or ignorant supervision, bad construction or impossible plans, may bring extra expense and bitter disappointment to them; and to him, an unfavorable reputation from which he will sufter through his whole professional life.

I have heard very many definitions of what an architect is. The most amusing one to me was from the simple son of a lady client. It was my unpleasant duty, at one stage of the work, to condemn a large piece of Credit Valley stone. The contractor in the presence of Bob, the son, was affirming very forcibly that he thought the stone was good enough, and expressed several other things that he thought. "Well," says Bob, "That's all right, Mr. ——, but there's a man paid to do the thinking."

There was a lesson in the remark for me, and to every conscientious architect, to be always thoughtful of his work, considering every detail—that the design be most suited to the purpose for which it is intended and to the purse of the owner—that from the foundation to the ridge every constructional problem be thoroughly considered, and that when completed the building will be beautiful. We will then find we shall have the mightiest of all proofs of success, that our clients will come to us for plans the next time they build, and use their influence with others on our behalf.

* Paper read by Mr. H. Simpson, read at the fifth annual convention of the Ontario Association of Architects.

HAMILTON.

(Correspondence of the CANADIAN ARCHITECT AND BUILDER.)

A special committee of the Hamilton City Council have recently recommended that the building by-law be amended by extending the fire limits, and providing that all schools, theatres, and other public buildings shall have fire escapes attached, and that no explosives be permitted to be stored in any building. The owner or contractor is made liable for the infraction of the by-law. The fire limits, which at present are Bay street on the west, John street east, the mountain on the south, and the Grand Trunk railway on the north, are to be changed to Wentworth street on the east, from the Grand Trunk Railway to the Northern and North-Western track, thence west to Ferguson avenue, south to Aberdeen avenue, west to Locke street, north to King street, west to Dundurn street, north to the Grand Trunk railway tracks, thence in a south-east direction to Queen street, south along that street to York street, east to Hess, north to Cannon, east to Bay street, and north to the Grand Trunk railway. Builders will be required to deposit with the inspector a ground plan of the buildings. Nothing but stone or brick buildings will be permitted to be erected within the fire limits.

MONTREAL.

(Correspondence of the CANADIAN ARCHITECT AND BUILDER.)

Mr. Geo. E. Wade, R. A., of London, Eng., who won the competition for designs for a memorial statue to the late Sir John A. Macdonald, to be erected on Dominion Square, in this city, has sent a representative here in the person of Mr. F. A. Williams to make the preliminary arrangements. The statue is to cost $20,000, which amount has already been subscribed. It will stand on a base of unpolished granite, 12 feet in height, with steps on the four sides leading up to the pedestal of the main statue. The statue itself will be surrounded by twelve polished red granite clustered columns fourteen feet in height, and with bronze caps. Resting on these columns is a stilted arch nine feet in height, with reliefs in bronze, emblematical of Canada's progress. Resting on the arch are four colossal lions in bronze, and above these stand a group of seven figures, holding shields and linked arm-in-arm to represent the seven provinces of the Dominion, which were confederated by Sir John Macdonald. In the centre of these figures, and overtopping them, will be the statue of the Queen of Plenty, holding in her hand a cornucopia filled with Canadian products. Different bronzes, representing the various industries of the country, are placed at the base of the pillars. The model of the statue has been completed by Mr. Wade, and has been approved by Her Majesty, the Queen, and the Prince of Wales. The impression prevails that the winners of the second and third prizes in this competition will be declared to be Mr. Griffiths, of London, Eng., and Signor Xeniéres, of Rome.

Contracts are about to be let for the erection of the Canada Life Association's new office building, plans for which have been prepared by Mr. Waite, of Buffalo. The building, which has been designed in the free Renaissance style, will consist of seven stories and a basement. It will stand at the corner of St. James and St. Peter street, extending back to Fortification Lane. It will have a frontage of 58 feet on St. James street. The frame work will be of steel, encased in fire proof materials and faced with Ohio blue stone. There will be two principal entrances, on James and St. Peter streets respectively. Offices for the owners will be arranged on the first floor; the ground floor story is to be occupied by the Canadian Bank of Commerce.

Referring to the appointment of a committee by the Architectural League of New York to draft an ordinance to forbid the erection of buildings of excessive height, on the ground of their being insecure, insanitary and inartistic, the Insurance and Finance Chronicle, of this city, says: If the action of the architects is backed up by the insurance companies, and all who have judgment enough to realize how health must be endangered by streets running through deep defiles of buildings that keep out sunlight and air, there will be a limit placed on these Babel-like structures.

A dinner was recently tendered at the St. James club, in this city, to the Hon. Mr. Nantel, Provincial Commissioner of Public Works, on the eve of his departure on an extended trip to Europe and the Holy Land.

The Building Inspector reports that the number of buildings erected during 1893 was 561 as compared with 640 in the previous year. The value of the buildings erected last year was $2,835,800, as against $2,508,825 in 1892, thus showing the buildings put up last year to have been of a much superior class to those of the previous year. As the result of his recent visit to the convention of Building Commissioners and Inspectors of the United States, Mr. Lacroix will recommend that our building ordinance be amended so as to provide for the erection of fire escapes to a much greater extent than heretofore.

An old stone front building in the rear of the Home of the Sisters of Notre Dame collapsed recently, throwing into the street the walls and windows of the third story. Fortunately no one happened to be passing at the time; if there had been, one or more deaths would have to be recorded. This occurrence points to the necessity for frequent and careful inspection of old structures which front on public thoroughfares. It is due to our Building Inspector to say that he has usually shown himself to be thoroughly alive to the duties of his position in this regard.

The fifteenth annual spring exhibition of the Montreal Art Association will be opened on April 29th next in the galleries of the Association, and will close on May 9.

STUDENTS' DEPARTMENT.

"CANADIAN ARCHITECT AND BUILDER" STUDENTS' COMPETITION.

IN connection with the Students' Competition for a Drug Store and Dwelling, the conditions of which were announced in the ARCHITECT AND BUILDER for February, we regret to state that the number of designs received was not sufficient to form a basis for the decision of the competition by a vote of the students as provided for by the conditions.

It may be that the time allowed for the preparation of the drawings was not deemed sufficient, and also that the time of a number of students who would otherwise have entered the competition was fully taken up with the Ontario Association of Architects examinations. In view of the possibility that these causes may have hindered the success of the competition, it has been thought desirable to extend the date when the competition will close to the 8th of April.

It is hoped that in consequence of this extension of time a larger number of students will decide to submit drawings. Should this hope prove to be ill-founded, the competition will necessarily be withdrawn.

INTERCOMMUNICATION COLUMN.

This column is intended to afford a means of correspondence for students, builders, and all our readers desiring information they cannot otherwise obtain. Questions for which an immediate reply is required should be marked "Urgent." Names and addresses of correspondents must be sent with their communications, but these may be signed with initials or otherwise for publication.

QUESTIONS.

[9]. I have had a present of $50 for the purchase of books most useful to me as a student of architecture and want advice how best to spend it? Could you get information for me in your new column.—BUDDING ARCHITECT.

[10]. An old stone barn in an exposed situation suffers much from the weather on one side. The stone it is built of is soft and though it was all carefully pointed up in the fall, the stone itself seems to need treatment. Can you tell me any method of preserving it that will be effectual as well as inexpensive?—J. B. M.

[11]. I should be glad if "G" [6] would give me some information as to what papers he would suggest for circulation in the proposed "Club." I should be pleased to join but would like to know about the expense proposed to be borne by each member.

[12]. The snow lies thickly on a church roof and what with the sun, and also the warmth of the building it sometimes slides off with a roar that drowns the voice of the preacher and considerably startles the congregation. Is there any way to prevent this?—N. J.

REPLIES.

[1]. "Analysis of Ancient Domestic Architecture," by Dollman & Gibbons, "Baronial Halls," by Harding and others, "Domestic Architecture in England," Turner.

[2]. H. W.—There can be no doubt that hollow walls properly constructed, have many advantages over solid walls. It is best to build them with the air space as near the exterior as possible, i.e., in a brick wall, the air space should be next to the half brick facing, but in a stone-faced wall the air space must necessarily be against the internal brick work. Careful bonding of the thin portion to the thick, is a *sine qua non*, as also is a damp preventing course at the bottom of the air space; the inside face of the outside brick or stone face should be well parged, and if these precautions are taken a hollow wall will be a great improvement to a building.—P. M.

[2]. H. W.—I would recommend "H. W." to read what is said about "Hollow Walls" in Vol. II. "Notes on Building Construction," (South Kensington).

[4]. "Builder":—You say your contract does not say anything about the time for *final* payment; does it say anything about payment by certificate?—there may be a clause which covers the whole subject; I can hardly understand a contract without such particulars. Without a stipulated time for payment the architect's certificate does not bind the owner to pay at a stated time. I suppose your only remedy would be under the "Mechanics' Lien Act." Great care should be executed in dealing with such questions as this, and without the fullest particulars of the case, I can hardly venture to advise. I would recommend you to see your lawyer and suggest to him to study "Mechanics' Legal Hand Book" before advising you.—L. A. W.

[5] "Quebecer."—If you "invoke the aid of the law" to set you free, you would find that your "written agreement" was binding upon you, unless there is a clause in reference to the point raised. You have apparently been fifteen months at the profession; to do nothing but "kick your heels" would seem a waste of time certainly. Instead of having any unpleasantness with your employer, your wisest course is to ask him to help and direct you in a course of study, to prepare for being of greater use to him when more busy days arrive and to fit you for the examinations which you ought to go up for. You should have gone up for the "first intermediate" this month. Look up the published questions of last years O. A. A. examinations and see if you can answer them; if not, here is a field with which to occupy yourself with great profit. You should be able to answer all these questions after being fifteen months in an architect's office.—[ED. "INT. COL."

[7] "Jack."—The only way of mounting tracings on drawing paper so as not to injure them when rolled up, is to stick down one side and leave the others loose. It should be the top side, and it should then be rolled from this side; that, however, can hardly be called "mounting."—J. C.

[8]. "Architect."—Write to Mr. C. H. C. Wright, of the School of Practical Science, Toronto, who, from tests of cement made at the institution, could no doubt tell you the most reliable brands for your work in the country. Being at a distance you cannot easily get your cement tested, of course. Possibly one or two rough methods of test may help you. Fill a bottle with a paste made with neat cement and let it stand for a few days, if the cement is not in good condition it will expand and crack the bottle, or if it has not been burnt enough the cement will shrink slightly. Plunge your bare arm into the cement; if it feels cold it is bad, if hot it requires more turning over; to be good it should be pleasantly warm to the skin. I have known some fairly eminent men make use of the latter test when no other means were at hand.—"ARCHITECTUS."

N. B.—With reference to the suggested "Reading Club," we are sorry that we have not heard from more students so far, but when "G" answers the question which appears this month about it, we shall be somewhat surprised if there is not a rush to take advantage of it. The expenses we should think would not be more than a dollar (perhaps less) to each member.—[ED. "INT. COL."

[13]. Where and of whom can we procure a book on bricklaying?—J. R. & SON, Dorchester, N. B.

[13]. We can procure for you any of the following books on bricklaying:—"Useful Information for Bricklayers," being an improved method for setting out ganged arches, by J. Buckle, price $1.00; "Drawing for Bricklayers" by E. A. Davidson, illustrated, $1.50; The Rudiments of Practical Bricklaying," by A. Hammond, including general principles of arch-drawing, cutting and setting, pointing, paving, tiling, etc., illustrated, intended to be a hand book for apprentices and beginners, 60 cents; "Practical Brick Cutting and Setting," by the same author, illustrated, 108 pages, 60 cents; "Brick Work," a practical treatise on the higher principles of cutting and setting and the application of geometry to roof tiling, etc., two editions, illustrated, 60 cents each edition.—ED. INT. COL.

USEFUL HINTS.

Paste may be kept several months without getting mouldy if a little pulverized blue stone is added while hot.

Professor Laurie in a recent lecture at the Society of Arts, stated that there are at least two preparations on the market which are as valuable commercially as white lead, whilst they lack its qualities which are so harmful to human life. These are sulphate of lead and oxide of zinc. A mixture of the two, known as "Freeman's White," has been proved to have a greater covering power as a pigment than white lead, whilst oxide of zinc keeps its color for a much longer time in impure air, and is therefore valuable for interior work.

TAR PATHS.—Secure a firm foundation, and slope the ground with cinders or gravel, allowing a quick run towards the gutter. Sift furnace ashes through ¼in. screen and well mix with gas tar, lay on a layer ¾in. thick, well tread down, and finish by continually rolling, sifting over a little dry ashes and lime to prevent roller sticking. The greatest art is in finding how much tar is required to "set" the ashes, and not to put more, or it will be soft and spongy in warm weather. No absolute rule can be laid down, as much depends both upon the quality and nature of ashes. Try a small piece first, measuring both tar and ashes, use your own judgment as to the proportions. Do not boil the tar.

EXPANSION OF GIRDERS.—A writer on strains in girders referring to the amount of movement of iron girders due to expansion and contraction under extreme variations of temperature, observes that for iron and steel the coefficient or rate of expansion is nearly 1 inch for 100° of heat (F.) for every 100 feet in length. Thus a girder 60 feet in length will expand sixtenths of an inch for 100° increase of temperature, and contract the same amount for 100° decrease of temperature; or a girder 75 feet long will vary seventy-five-one-hundredths of an inch, or ¾ inch, for a variation of 100°. He says: "In order to provide for all contingencies it is the general practice to allow for a vibration of 100° F., or a movement equal to 1½ inches for every 100 feet in length." A girder 60 feet long will therefore require to have an allowance for movement in the moving end equal to nine-tenths of an inch or 1 inch, the other end being fixed. It is only necessary to put the rollers under one end of the girder, so that the movement of the girder may be at that end only.

FIREPROOF WHITEWASH.—A most effective composition for fireproofing exterior surfaces may be formed by slacking a sufficient quantity of freshly-burned quick-lime of the best grade, and, when slacking is complete; there is added such an amount of skim milk, or water in its absence, as will make the liquid of the consistency of cream. To every ten pounds of this liquid is added separately and in powder, stirring constantly, the following ingredients in the order named: Two pounds of alum, twenty-four ounces of sub-carbonate of potassium or commercial potash, and one pound of common salt. If white paint is desired, a further addition is made to the liquid, though the whiteness is found to be improved by the addition of a few ounces of plaster of Paris. Lampblack has the effect of giving it a number of shades from slate color to black. Whatever tint is used, it is incorporated at this stage, and the whole, after being strained through sieve, is run through a paint mill. When ready to apply the paint is heated nearly to the boiling point of water, and is put on in its hot condition. It is found that the addition of a quantity of fine white sand to this composition renders it a valuable covering for roofs and crumbling brick walls, which it serves to protect.

THE ARCHITECT.*

As this is the first time that I have had the pleasure of reading a paper either before architects or others I sincerely trust that you will bear with me, look kindly upon any errors I may make, and if the paper as a whole be weak I hope you will be light in your vituperation and that I may be strengthened in this to better prepare another at some other time. I have chosen as you see for a subject "The Architect."

It has been said that any one possessing the knowledge of a poor carpenter, the skill of an indifferent draughtsman, a little audacity and a ten dollar bill, can appoint himself an architect. Certainly in the present state of affairs all persons are privileged alike in practising architecture, or rather in, shall I say, designing, and superintending the construction of buildings, notwithstanding the important consideration of health and safety of life involved, to say nothing of the hideous aberrations that our cities and towns are often besmeared with by men whose only passport to public patronage is their "gall" and the assumption of the name of architect.

It seems a pity that something cannot be done to limit the practice of architecture to properly qualified men. I have sometimes thought that instead of having the word "Registered" removed from Clause 25 of the Ontario Architects' Act, that those only who have passed examination be allowed to call themselves "Registered"; all others who though still being allowed to practice, would not term themselves "registered architects" and thus save the ignorant public, if they choose, from being victimized.

I have also thought a measure of the trouble might be averted, the beauty of the city improved and the architectural profession edified, if the city would not grant a permit for any building unless a copy of the plan as made by, and bearing the signature of an architect be filed, and if the architect would not undertake to make plans for any person unless he be commissioned to superintend the construction of the building as well.

Loan companies and money lenders would have better security for their money if they would insist that the building on which they are asked to advance money should be planned and superintended by an architect.

But before the general public will be able to distinguish between architects and ARCHITECTS, it will necessary that they be educated to distinguish between good and bad architecture—to accomplish which there is no doubt this Association has done and is doing a great deal, but perhaps if architects would voice their opinions through the press oftener on things architectural the matter would receive more consideration from the public. The taste of the coming generation would be greatly cultivated along this line if the study of architecture were brought into our public schools. In whatever way this great change shall be brought about I cannot say, but I sincerely trust that the time is not far distant when incompetent men, such as real estate agents and mechanics, will not be allowed to practice architecture without the proper qualifications.

How often we see exemplified the sarcasm of Lessing when he says—

> Tomkins forsakes his last and awl
> For literary squabbles,
> Styles himself poet
> But his trade remains the same—he cobbles.

I remember hearing of one of this stamp erecting a large building for manufacturing purposes where all the internal supports were wooden posts from basement floor to roof; the weight to be imposed on each support would be something enormous. Under each post he had one stone 18" × 18" × 9" resting on the earth, and but for the better judgment of the builder who objected to carrying out the plans in this respect, there would probably have been very disastrous results. This architect, with fear and trembling, went to the owner and made the excuse that owing to the softness of the earth which he had not foreseen, it would be necessary to enlarge the footings under the posts.

When we hear such things as this about people who call themselves architects, we can hardly wonder at owners employing what is known as the "practical man," instead of an architect, for this kind of work.

Plagiarism, or purloining the designs of others and calling them your own, is, unfortunately practiced by this class of people who usurp the name of architect, who, if they do not crib the entire design, pick out the features they think suitable for their purpose from the published work of other architects and who manage in this way to form some sort of a design, and hearing whatever praise the unsuspecting client may have given expression to, he "bears his blushing honors thick upon him" just as if they had been honestly merited. I remember being asked to compete for a small country church. Out of respect for the feelings of the kind friend through whose influence I was asked, I submitted plans, but was not, however, the fortunate man. In conversation with the secretary of the Building Committee he informed me that he had in his possession one design which met with the approval of the committee. He showed me the plans and perspective drawing, the latter being a tracing from the CANADIAN ARCHITECT AND BUILDER of a published design which I myself had made.

Dryden has aptly marked the three steps in the career of most men of genius, thus—

> "What the child admired
> The youth endeavored and the man acquired."

In my mind I can scarcely conceive of a man being proficient in this profession whose career has not been marked by these three steps—one who has studied the profession from his early youth, spent a number of years in the office of a recognized member of the profession at all kinds of work in connection with architecture, and who makes a constant study of his profession.

It is perhaps a misfortune of the profession that its members must be at once artists, business men and scientific experts, and they cannot choose to be either more than the other without great injury to their usefulness and success. It is thought by a great many to be beyond human capacity to excel in design and anything else at the same time. The man who would be a thorough architect, while taking great pleasure in exercising his designing qualities, should not overlook the importance of making constant efforts to keep himself familiar with details of construction, prices and specifications.

It is often found that an architect for fear of discouraging his client at the beginning, systematically makes all sorts of encouraging responses to enquiries regarding the cost, and does everything to get a building started; so the owner after having seen a most elaborate sketch is tempted to go on with the work, although the tenders have now exceeded his appropriation by say $2,000. Afterwards tenders are to be taken for mantels, gas fixtures, heating, etc. Of course the architect told him that these were not included in the original estimate, but he had no idea they would run into so much money; so that when the building is completed it has cost several thousand dollars more than he intended. The owner in his discouragement of course blames the architect. If the architect had spoken plainly to his client in the first place and told him he was expecting too much for the money, all the trouble would most likely have been prevented. There is far more merit in being able to build well on a minimum allowance than to design artistically, but unfortunately without any regard for cost. What credit is it to the architect who makes a pretty building where cost has not been a consideration?

The architect should bear in mind that his first clients will generally be his personal friends, and that defective specifications or ignorant supervision, bad construction or impossible plans, may bring extra expense and bitter disappointment to them; and to him, an unfavorable reputation from which he will suffer through his whole professional life.

I have heard very many definitions of what an architect is. The most amusing one to me was from the simple son of a lady client. It was my unpleasant duty, at one stage of the work, to condemn a large piece of Credit Valley stone. The contractor in the presence of Bob, the son, was affirming very forcibly that he thought the stone was good enough, and expressed several other things that he thought. "Well," says Bob, "That's all right, Mr. ——, but there's a man paid to do the thinking."

There was a lesson in the remark for me, and to every conscientious architect, to be always thoughtful of his work, considering every detail—that the design be most suited to the purpose for which it is intended and to the purse of the owner—that from the foundation to the ridge every constructional problem be thoroughly considered, and that when completed the building will be beautiful. We will then find we shall have the mightiest of all proofs of success, that our clients will come to us for plans the next time they build, and use their influence with others on our behalf.

* Paper read by Mr. H. Simpson, read at the fifth annual convention of the Ontario Association of Architects.

HAMILTON.

(Correspondence of the CANADIAN ARCHITECT AND BUILDER.)

A special committee of the Hamilton City Council have recently recommended that the building by-law be amended by extending the fire limits, and providing that all schools, theatres, and other public buildings shall have fire escapes attached, and that no explosives be permitted to be stored in any building. The owner or contractor is made liable for the infraction of the by-law. The fire limits, which at present are Bay street on the west, John street east, the mountain on the south, and the Grand Trunk railway on the north, are to be changed to Wentworth street on the east, from the Grand Trunk Railway to the Northern and North-Western track, thence west to Ferguson avenue, south to Aberdeen avenue, west to Locke street, north to King street, west to Dundurn street, north to the Grand Trunk railway tracks, thence in a south-east direction to Queen street, south along that street to York street, east to Hess, north to Cannon, east to Bay street, and north to the Grand Trunk railway. Builders will be required to deposit with the inspector a ground plan of the buildings. Nothing but stone or brick buildings will be permitted to be erected within the fire limits.

MONTREAL.

(Correspondence of the CANADIAN ARCHITECT AND BUILDER.)

Mr. Geo. E. Wade, R. A., of London, Eng., who won the competition for designs for a memorial statue to the late Sir John A. Macdonald, to be erected on Dominion Square, in this city, has sent a representative here in the person of Mr. F. A. Williams to make the preliminary arrangements. The statue is to cost $20,000, which amount has already been subscribed. It will stand on a base of unpolished granite, 12 feet in height, with steps on the four sides leading up to the pedestal of the main statue. The statue itself will be surrounded by twelve polished red granite clustered columns fourteen feet in height, and with bronze caps. Resting on these columns is a stilted arch nine feet in height, with reliefs in bronze, emblematical of Canada's progress. Resting on the arch are four colossal lions in bronze, and above these stand a group of seven figures, holding shields and linked arm-in-arm to represent the seven provinces of the Dominion, which were confederated by Sir John Macdonald. In the centre of these figures, and overtopping them, will be the statue of the Queen of Plenty, holding in her hand a cornucopia filled with Canadian products. Different bronzes, representing the various industries of the country, are placed at the base of the pillars. The model of the statue has been completed by Mr. Wade, and has been approved by Her Majesty, the Queen, and the Prince of Wales. The impression prevails that the winners of the second and third prizes in this competition will be declared to be Mr. Griffiths, of London, Eng., and Signor Xeménes, of Rome.

Contracts are about to be let for the erection of the Canada Life Association's new office building, plans for which have been prepared by Mr. Waite, of Buffalo. The building, which has been designed in the free Renaissance style, will consist of seven stories and a basement. It will stand at the corner of St. James and St. Peter street, extending back to Fortification Lane. It will have a frontage of 58 feet on St. James street. The frame work will be of steel, encased in fire proof materials and faced with Ohio blue stone. There will be two principal entrances, on James and St. Peter streets respectively. Offices for the owners will be arranged on the first floor; the ground floor story is to be occupied by the Canadian Bank of Commerce.

Referring to the appointment of a committee by the Architectural-League of New York to draft an ordinance to forbid the erection of buildings of excessive height, on the ground of their being insecure, insanitary and inartistic, the Insurance and Finance Chronicle, of this city, says: If the action of the architects is backed up by the insurance companies, and all who have judgment enough to realize how health must be endangered by streets running through deep defiles of buildings that keep out sunlight and air, there will be a limit placed on these Babel-like structures.

A dinner was recently tendered at the St. James club, in this city, to the Hon. Mr. Nantel, Provincial Commissioner of Public Works, on the eve of his departure on an extended trip to Europe and the Holy Land.

The Building Inspector reports that the number of buildings erected during 1893 was 561 as compared with 640 in the previous year. The value of the buildings erected last year was $2,835,800, as against $2,508,825 in 1892, thus showing the buildings put up last year to have been of a much superior class to those of the previous year. As the result of his recent visit to the convention of Building Commissioners and Inspectors of the United States, Mr. Lacroix will recommend that our building ordinance be amended so as to provide for the erection of fire escapes to a much greater extent than heretofore.

An old stone front building in the rear of the Home of the Sisters of Notre Dame collapsed recently, throwing into the street the walls and windows of the third story. Fortunately no one happened to be passing at the time; if there had been, one or more deaths would have to be recorded. This occurrence points to the necessity for frequent and careful inspection of old structures which front on public thoroughfares. It is due to our Building Inspector to say that he has usually shown himself to be thoroughly alive to the duties of his position in this regard.

The fifteenth annual spring exhibition of the Montreal Art Association will be opened on April 20th next in the galleries of the Association, and will close on May 9.

STUDENTS' DEPARTMENT.

"CANADIAN ARCHITECT AND BUILDER" STUDENTS' COMPETITION.

IN connection with the Students' Competition for a Drug Store and Dwelling, the conditions of which were announced in the ARCHITECT AND BUILDER for February, we regret to state that the number of designs received was not sufficient to form a basis for the decision of the competition by a vote of the students as provided for by the conditions.

It may be that the time allowed for the preparation of the drawings was not deemed sufficient, and also that the time of a number of students who would otherwise have entered the competition was fully taken up with the Ontario Association of Architects examinations. In view of the possibility that these causes may have hindered the success of the competition, it has been thought desirable to extend the date when the competition will close to the 8th of April.

It is hoped that in consequence of this extension of time a larger number of students will decide to submit drawings. Should this hope prove to be ill-founded, the competition will necessarily be withdrawn.

INTERCOMMUNICATION COLUMN.

This column is intended to afford a means of correspondence for students, builders, and all our readers desiring information they cannot otherwise obtain. Questions for which an immediate reply is required should be marked "Urgent." Names and addresses of correspondents must be sent with their communications, but these may be signed with initials or otherwise for publication.

QUESTIONS.

[9]. I have had a present of $50 for the purchase of books most useful to me as a student of architecture and want advice how best to spend it? Could you get information for me in your new column.—BUDDING ARCHITECT.

[10]. An old stone barn in an exposed situation suffers much from the weather on one side. The stone it is built of is soft and though it was all carefully pointed up in the fall, the stone itself seems to need treatment. Can you tell me any method of preserving it that will be effectual as well as inexpensive?—J. B. M.

[11]. I should be glad if "G" [6] would give me some information as to what papers he would suggest for circulation in the proposed "Club." I should be pleased to join but would like to know about the expense proposed to be borne by each member.

[12]. The snow lies thickly on a church roof and what with the sun, and also the warmth of the building it sometimes slides off with a roar that drowns the voice of the preacher and considerably startles the congregation. Is there any way to prevent this?—N. J.

REPLIES.

[1]. "Analysis of Ancient Domestic Architecture," by Dollman & Gibbons, "Baronial Halls," by Harding and others, "Domestic Architecture in England," Turner.

[2]. H. W.—There can be no doubt that hollow walls properly constructed, have many advantages over solid walls. It is best to build them with the air space as near the exterior as possible, i.e., in a brick wall, the air space should be next to the half brick facing, but in a stone-faced wall the air space must necessarily be against the internal brick work. Careful bonding of the thin portion to the thick, is a *sine qua non*, as also is a damp preventing course at the bottom of the air space; the inside face of the outside brick or stone face should be well parged, and if these precautions are taken a hollow wall will be a great improvement to a building.—P. M.

[2]. H. W.—I would recommend "H. W." to read what is said about "Hollow Walls" in Vol. II. "Notes on Building Construction," (South Kensington).

[4]. "Builder":—You say your contract does not say anything about the time for *final* payment; does it say anything about payment by certificate?—there may be a clause which covers the whole subject; I can hardly understand a contract without such particulars. Without a stipulated time for payment the architect's certificate does not bind the owner to pay at a stated time. I suppose your only remedy would be under the "Mechanics' Lien Act." Great care should be executed in dealing with such questions as this, and without the fullest particulars of the case, I can hardly venture to advise. I would recommend you to see your lawyer and suggest to him to study "Mechanics' Legal Hand Book" before advising you.—L. A. W.

[5] "Quebecer."—If you "invoke the aid of the law" to set you free, you would find that your "written agreement" was binding upon you, unless there is a clause in reference to the point raised. You have apparently been fifteen months at the profession; to do nothing but "kick your heels" would seem a waste of time certainly. Instead of having any unpleasantness with your employer, your wisest course is to ask him to help and direct you in a course of study, to prepare for being of greater use to him when more busy days arrive and to fit you for the examinations which you ought to go up for. You should have gone up for the "first intermediate" this month. Look up the published questions of last years O. A. A. examinations and see if you can answer them; if not, here is a field with which to occupy yourself with great profit. You should be able to answer all these questions after being fifteen months in an architect's office.—[ED. "INT. COL."

[7] "Jack."—The only way of mounting tracings on drawing paper so as not to injure them when rolled up, is to stick down one side and leave the others loose. It should be the top side, and it should then be rolled from this side; that, however, can hardly be called "mounting."—J. C.

[8]. "Architect."—Write to Mr. C. H. C. Wright, of the School of Practical Science, Toronto, who, from tests of cement made at the institution, could no doubt tell you the most reliable brands for your work in the country. Being at a distance you cannot easily get your cement tested, of course. Possibly one or two rough methods of test may help you. Fill a bottle with a paste made with neat cement and let it stand for a few days, if the cement is not in good condition it will expand and crack the bottle, or if it has not been burnt enough the cement will shrink slightly. Plunge your bare arm into the cement; if it feels cold it is bad, if hot it requires more turning over; to be good it should be pleasantly warm to the skin. I have known some fairly eminent men make use of the latter test when no other means were at hand.—"ARCHITECTUS."

N. B.—With reference to the suggested "Reading Club," we are sorry that we have not heard from more students so far, but when "G" answers the question which appears this month about it, we shall be somewhat surprised if there is not a rush to take advantage of it. The expenses we should think would not be more than a dollar (perhaps less) to each member.—[ED. "INT. COL."

[13]. Where and of whom can we procure a book on bricklaying?—J. R. & SON, Dorchester, N. B.

[13]. We can procure for you any of the following books on bricklaying:—"Useful Information for Bricklayers," being an improved method for setting out gauged arches, by J. Buckle, price $1.00; "Drawing for Bricklayers" by E. A. Davidson, illustrated, $1.50; The Rudiments of Practical Bricklaying," by A. Hammond, including general principles of arch-drawing, cutting and setting, pointing, paving, tiling, etc., illustrated, intended to be a hand book for apprentices and beginners, 60 cents; "Practical Brick Cutting and Setting," by the same author, illustrated, 108 pages, 60 cents; "Brick Work," a practical treatise on the higher principles of cutting and setting and the application of geometry to roof tiling, etc., two editions, illustrated, 60 cents each edition.—ED. USEFUL HINTS.

Paste may be kept several months without getting mouldy if a little pulverized blue stone is added while hot.

Professor Laurie in a recent lecture at the Society of Arts, stated that there are at least two preparations on the market which are as valuable commercially as white lead, whilst they lack its qualities which are so harmful to human life. These are sulphate of lead and oxide of zinc. A mixture of the two, known as "Freeman's White," has been proved to have a greater covering power as a pigment than white lead, whilst oxide of zinc keeps its color for a much longer time in impure air, and is therefore valuable for interior work.

TAR PATHS.—Secure a firm foundation, and slope the ground with cinders or gravel, allowing a quick run towards the gutter. Sift furnace ashes through ¼in. screen and well mix with gas tar, lay on a layer 3in. thick, well tread down, and finish by continually rolling, sifting over a little dry ashes and lime to prevent roller sticking. The greatest art is in finding how much tar is required to "set" the ashes, and not to put more, or it will be soft and spongy in warm weather. No absolute rule can be laid down, as much depends both upon the quality and nature of ashes. Try a small piece first, measuring both tar and and ashes, use your own judgment as to the proportions. Do not boil the tar.

EXPANSION OF GIRDERS.—A writer on strains in girders referring to the amount of movement of iron girders due to expansion and contraction under extreme variations of temperature, observes that for iron and steel the coefficient or rate of expansion is nearly 1 inch for 100° of heat (F.) for every 100 feet in length. Thus a girder 60 feet in length will expand sixtenths of an inch for 100° increase of temperature, and contract the same amount for 100° decrease of temperature; or a girder 75 feet long will vary seventy-five-one-hundredths of an inch, or ¾ inch, for a variation of 100°. He says: "In order to provide for all contingencies it is the general practice to allow for a vibration of 100° F., or a movement equal to 1¼ inches for every 100 feet in length." A girder 60 feet long will therefore require to have an allowance for movement in the moving end equal to nine-tenths of an inch or 1 inch, the other end being fixed. It is only necessary to put the rollers under one end of the girder, so that the movement of the girder may be at that end only.

FIREPROOF WHITEWASH.—A most effective composition for fireproofing exterior surfaces may be formed by slacking a sufficient quantity of freshly-burned quick-lime of the best grade; and, when slacking is complete, there is added such an amount of skim milk, or water in its absence, as will make the liquid of the consistency of cream. To every ten pounds of this liquid is added separately and in powder, stirring constantly, the following ingredients in the order named: Two pounds of alum, twenty-four ounces of sub-carbonate of potassium or commercial potash, and one pound of common salt. If white paint is desired, a further addition is made to the liquid, though the whiteness is found to be improved by the addition of a few ounces of plaster of Paris. Lampblack has the effect of giving it a number of shades from slate color to black. Whateyer tint is used it is incorporated at this stage, and the whole, after being strained through sieve, is run through a paint mill. When ready to apply the paint is heated nearly to the boiling point of water, and is put on in its hot condition. It is found that the addition of a quantity of fine white sand to this composition renders it a valuable covering for roofs and crumbling brick walls, which it serves to protect.

CURRENT ARCHITECTURAL STYLES.*

By Grant Hellwell.

The title "current styles" somewhat imperfectly expresses the object of this paper. To do justice to a description of the current styles of architecture, at least in these days, would be altogether beyond the scope of a short paper, and moreover, while extremely interesting, and to a certain extent profitable, it is a question whether, in the limited time at our disposal, in a convention of architects gathered from different parts of the province, the opportunity cannot be better employed. The object, then, will be, not so much to attempt a full description of the many styles now prevalent, as to briefly review some of the more important of them; to endeavor to look beneath the surface and if possible ascertain the fundamental principles underlying architectural style, and from our investigation to deduce some conclusions as to how real progress may be made in the achievements of a profession than which there is none nobler in the realms of art or science.

The frequency with which, in matters pertaining to architectural design or buildings, the public propound to one the question "what style is it?", would be amusing were it not so often embarrassing. It is embarrassing fo rtwo reasons. In the first place it opens up the question "what is style"?—one by no means easy to define. A thoroughly logical definition of the term is seldom attempted. Gossfried Semper says: "style is the coincidence, in a work of art, with the history of its coming into reality, with all the conditions and circumstances that are causal to its origin." Another authority defines "style" as "the language in which we express our thoughts, the natural expression of our requirements in building." But for the purposes of this paper it is not necessary to go further; these two definitions are probably sufficient to convince anyone that an explanation of the term is not quite so simple as at first it may appear. In the second place, the conundrum arises, respecting the building or design in question. "Has it any style, and if so what?" The answer to this may be more difficult than the first. True, if the building were a copy of one of the structures of ancient Greece or of one of the scarcely less famous cathedrals of the mediaeval period, it would be easy for the veriest tyro to name its style correctly. Incomparably beautiful, however, in their respective classes, as those buildings were, their exact reproduction in modern times is usually deemed a ludicrous mistake. The customs, manners and conditions generally, under which they were erected, belong to a by-gone age, and charming as such structures might be to the eye, they would, except in rare caese, wanting in two of the chief elements of the highest art, viz., by utility and truth. But for the most part the buildings on whose style we are called upon to pronounce are of a very different stamp. Erected to fill many requirements, and restricted by innumerable conditions, the average modern erection is of a complex character. In many instances, perhaps the majority, it is more than doubtful whether the building possesses any style at all. In others, the taste and skill of the designer have produced a building, having an unmistakable air of character and individuality, but of whose style, in the ordinary sense of the term we are not so certain.

In proceeding to discuss styles of architecture, while we are primarily and chiefly interested in the architecture of our own Canada, we must, without any disloyalty or self reproach, admit that while we have produced work, which, in its class, compares favorably with that of any country, we are, architecturally, overshadowed, on the one hand, by the great and wealthy nation to our south, and on the other, by the head of that mighty empire of which we are proud to form a part, and to the architecture of of these two countries let us now direct our attention.

In reviewing current architecture in England, the traditions of the past are so intimately connected with modern work, that it may not be amiss briefly to refer to the early history of the art. Beginning with the crude ideas introduced at the time of the Norman Invasion, the progress of architecture as it slowly developed into the various phases of gothic is clearly marked in the buildings which still remain as monuments of English art. With the exit of the Tudor style a new and outside influence can be plainly descerned.

Renaissance forms appear, first of a German and Flemish type, followed later by evidences of Italian and French inspiration, culminating in that grand achievement, the pride of all England, St. Paul's cathedral. Since then the course of English architecture, at no time a particularly smooth one, has taken it through many vicissitudes. From the classic to the gothic, and from there to the renaissance again, first of one period, then of another, such has been its course. The gothic revival of the present century, ending perhaps with the erection of the London Law Courts by Street, was the last of anything approaching a uniform style. Since that time a spirit of eclecticism, the doctrine of selection, has reigned supreme. Every architect has felt free to choose this or that style as his fancy dictated, and the result has been an infinite variety of forms. This system prevails in England to-day, so that the term "current styles," as far as British architects are concerned, is a most comprehensive one. To those few men gifted with exceptional talent, this has been no particular drawback. It has developed in a special manner their individuality. This is markedly apparent in the work of Norman Shaw, whose buildings, familiar to us all, delightfully charming in their scholarly picturesqueness, their freedom from conventionality, are a standing testimony to his genius, and yet they cannot be classed under the head of any known style, although possessing that quality in a strong degree. Another master in English art is his contemporary, Waterhouse, whose versatility is not less noticeable than his artistic talents. Although he has perhaps achieved his greatest successes in the Romanesque style, an illustration of which is one of the most ooted of modern English buildings, the South Kensington Museum, a view of which will be shown us presently, the Manchester Assize Courts and the Town Hall in the same place, both in the gothic style, gave him a world wide celebrity, while his masterly treatment of the National Liberal Club building, is an example of his genius in renaissance art. Time forbids mention of some of the best recent work by other well known British architects, designed, for the most part, in some phase of Italian renaissance, though by no means wholly in that style. But it is an undeniable fact, that with certain few exceptions, English architecture of the last decade, shows little progress.

Interesting and instructing as it is to study the architectural types of English building art, it is with even keener interest and greater profit that we turn our attention to prevailing styles in America, for though bound by ties of kinship and political sovereignty to the mother land, in all those conditions which affect the subject of our discussion here, we have much more in common with our near neighbors on this side the Atlantic. We have the same climate and practically the same building materials, and even in our modes of living, our methods of business and all the environments of national life, we are more closely allied to them than to our honored head. So that the consideration of current styles in the United States may apply equally to Canada, and for the purposes of this discussion we will consider both countries as one.

Any review of American architecture, apart altogether from the ancient buildings of Mexico, is necessarily brief, being of such recent beginning as almost to deny it a history.

A nation of Anglo Saxon origin, and that not so very far back, nothing worthy of the name of architecture in its buildings dates over 200 years, and until comparatively recent times it has followed so closely in the lead of England that what has been said of the latter country is quite applicable to the new land. About the time of the birth of the Republic a modified classic style prevailed, now known as the Colonial, and many of the buildings of that era still remain to testify to the chaste and simple beauty with which they were clothed. But after this a decided retrogression took place, and for the greater part of a century few if any new buildings were erected having any claim to style. It was not until the beginning of the last quarter of this century that a distinctly new era in the architecture of the western world set in. That the restless vigor and energy so characteristic of the American people, and which in every other line has forced its achievements to the front, should remain quiescent in matters architectural, was not to be expected, and about the time above mentioned the bonds and shackles of traditional art were thrown off and an advance made into new fields of effort. The progress made has been most marked. Doubtless to the late H. H. Richardson more than to any other single individual is due the credit of the appearance, not of a new style, but of a new principle in American architecture. Trained in the modern Renaissance as taught in the schools of France, he early broke free from the limits of that style, and with his strong individuality took up the study of the round arch architecture prevailing in Europe prior to the gothic era, commonly known as Romanesque. In the hands of such a master work was produced which soon attracted the atten ion of his contemporaries and of the public. He above all men in his generation was the brightest example of that rare genius which can perceive and evolve the hidden beauties and possibilities of the work of past ages. Without slavishly copying, he was able to draw inspiration from every source and adapt it to the varying requirements of his art, and thus produced work which, while it bore the stamp of his own personality, challenged by its beauty and dignity, the admiration of all beholders. It is impossible to say to what degree of perfection, had he lived, he might have carried his chosen style. Apparently his mantle has not fallen on any of his successors. True, the influence of his work has been felt far more since his death than while he was amongst us. Like a tidal wave the fashion—for so we may call it—for Romanesque swept the land from ocean to ocean. Many large and attractive buildings were and are still being erected in that style. Some enthusiastic but superficial observers loudly hailed it as the long called for American style. But it was short lived. Richardson had many weak imitators, but few true followers; they copied the *forms*, but with the underlying principles that guided the master mind, with that power of adaptation, that fulness of resource possessed by him, they were unendowed. What was the result? Buildings, *said to be Romanesque*, rose by the thousand all over the continent, and the noble and dignified round-arch style was deposed from the lofty throne on which its greatest exponent had placed it to a position almost of contempt. As a consequence, those who did appreciate its charms and possibilities, and who, according to the measure of their ability, were thoughtfully and successfully working out the problems committed to their hands, forsook the style entirely and sought new

* Paper read at the fifth annual Convention of the Ontario Association of Architects, Toronto, Jan. 17, 1893.

motifs from other sources. Their methods of study and differences of taste led them in various directions; the spirit of eclecticism prevailed, and is still dominant.

There had been, even when the Richardsonian movement was at its height, some few men who had never inclined to the popular style; educated like him, in the French schools of architecture, thoroughly trained in and imbued with Classical art, they had remained true to their early training and had all along been producing good work of the Classic and Renaissance types. The waning of the Romanesque brought this style of design into special prominence, and the reaction which followed the surfeiting of the public taste with the characteristic freeness and irregularity of the former only served to render the symmetry and precision, the studied proportions, the refined and delicate detail of the beautiful Renaissance the more attractive. The example of these leaders, prominent among whom may be mentioned the names of R. M. Hunt and McKim, Mead and White, was soon followed by other members of the profession, and the new order of things quickly spread. About this time the projected Columbian Exposition at Chicago offered an unprecedented opportunity for architectural achievement, and the selection of Renaissance and Classic styles for its principal buildings and the subsequent successful carrying out of the designs was all that was needed to make these styles, perhaps even more popular than the Romanesque in its palmiest days. Still, though no other style or styles can fairly be considered as in the field for popular favor, the disciples and exponents of many other types of architecture are not idle, nor do they fail to find an appreciative and responsive public. The variety of style as exhibited to-day in all classes of buildings is simply amazing. A walk through a residential street in almost any of our cities or larger towns affords a striking confirmation of this fact. Here for instance, we may see a large imposing residence, the great detached columns in the Ionic or Corinthian order extending through two stories and supporting the entablature with its low, broad pediment, the wide verandahs, the central doorway with semicircular fanlight, the broad square topped windows with moulded architraves, all tending to carry one back to the old Colonial days. Close by is a handsome dwelling with a high steep roof with ornamental ousting, the circular corner bays rising through the several stories and terminating in a graceful pointed roof, dormer windows, large and high, with slender crocketted pinnacles and sweeping lofty pediment and finial, window and door openings with ornamented pilasters of slight projection and moulded enriched cornices, all with a degree of symmetry and balance and loftiness, strongly suggestive of the French chateau. Across the way, possibly, is a dwelling of Elizabethan type, with coped gables of fanciful and pleasing outline. On a little farther, and we pass several residences in what we will call for want of a better name, the American dwelling house style,—lower story built of brick or rough faced stone, above this the walls and gables faced with shingles, sometimes without color other than the soft silver grey tint produced by the weather, but oftener stained in some of the pleasing hues of brown or olive here is a tastely designed oriel window, there a cosily recessed and deeply shaded balcony; on one side the simple outline of the roof is broken by a graceful turret or dormer, on another it descends with sweeping curve to form the roof of a verandah. The general contour is certainly pleasing, the outline often picturesque, and there is an unmistakably homelike air about the whole that attracts in spite of many eccentricities and incongraities. It may be called the typical American home, in the production of which American architecture has gained its greatest success. But we are pre-eminently a commercial people and may naturally look to the buildings devoted to commerce in order to gauge the architectural progress of the day.

In any reference to current architecture in this country, the business buildings take a conspicuous place and we will briefly discuss some of their most characteristic features. And here, as nowhere else, has been brought to our architects a problem for the solution of which there was absolutely no precedent. The tremendous expansion of trade and commerce during the last two or three decades, has correspondingly increased the value of land in our great commercial centres and has necessitated the construction of those enormously high buildings which are the wonder, if not the admiration, of all who visit us. These buildings of 12, 15 and even 20 stories have been adversely criticized by some; but was it to be expected that in such an entirely new departure no mistakes would be made? The wonder rather is that such a measure of success as has unquestionably been achieved in the case of not a few of these gigantic buildings, should have been attained in view of the extreme difficulties of the problem. In perhaps the majority of instances the designing of these tall constructions, in which the height is so greatly disproportioned to the width, has been so skillfully managed by the disposition of the horizontal lines that the effect of height has been to a large extent obscured. The Romanesque style has been most happily employed in many cases, the usual disposition of the parts as seen in European mediaeval structures lending itself admirably to the requirements of the design which is commonly composed of a basement boldly and massively treated comprising two or three stories, then a central division of several stories in height with disposition of arches, the whole composition terminating in an attic of two or three stories. In the most successful buildings the angles have been admirably managed so as to give the appearance of strength and dignity necessary in structures of such size. Some of the later designs are in the popular Renaissance style and show a very clever treatment of the problem.

A word as to prevailing styles in ecclesiastical work. In a nation of such cosmopolitan character as America, embracing an almost innumerable variety of religious beliefs, it might be expected that great differences of style would be found, and such is the case. Romanesque, Gothic, Mauresque, Spanish and many other types are represented, though for the most part, it must be admitted to the discredit alike of their designers and the congregations for whom erected. In no class of architecture have the Americans so much to learn as in their church buildings. Still in their more recent works, signs of improvement are not wanting. The notable competition, a few years since, for the great Episcopal cathedral of New York has done not a little to advance ecclesiastical architecture. Although, as poicted out previously, a great variety of styles prevails in church work, it is doubtful if any are as appropriate for this class of building as the beautiful gothic forms, and the latest designs of perhaps a majority of our leading architects clearly point to this conclusion.

In her public and legislative buildings, with one or two notable exceptions, America has less claim to congratulation than in other architectural achievements, although here too, the most recently designed buildings show vast improvement over earlier work. No reference to American architecture is complete without allusion to the Capitol at Washington, a building of which any nation might well be proud. Although it cannot be termed a modern building, yet, inasmuch as the style in which it was built is more popular to-day than when it was designed, a reference to it is specially appropriate here. It is too well known to need description, and it is questionable if a structure of such stately dignity and grandeur will ever cease to exert a powerful influence on the architectural productions of the American people. In this sketch of current American architecture may be seen much that is encouraging. That there is an abundance of life and vigor is evident and that the character of our work has steadily and rapidly improved is equally apparent. Probably one of the most perplexing circumstances presented to our minds is the great variety of styles seen in our modern buildings, a spirit of restlessness, a lack of definite purpose which would seem necessary for the proper development of our art. Why is this so? Possibly one reason may be the deeper and fuller knowledge of the architectural styles of the past. If this is the case there need certainly be no fear as to the result, bearing in mind the fact that such knowledge includes not only an acquaintance with the form, but what is of vastly greater importance, a perception of the idea, of the principles underlying the outward form. To possess this knowledge and the power to apply it, requires patient thought and study, but there is no other royal road to the true development of architecture. Or again a reason may be the search after new elements of beauty, fresh and varied forms of architectural expression. This too need cause no alarm. Have we not in the works of nature an infinite variety of beautiful forms from the designs of the Divine Architect refreshing and delightsome to our senses. Can we wonder then in this age of versatility, of the ever changing forms of architecture? The impressive and stately monuments of classic art cannot satisfy every condition of aesthetic taste and it is doubtless in response to this characteristic of our nature, that we may see, in the case, for instance, of domestic architecture, the signs of a return to the picturesque and quaint beauties of the half timbered houses of a decade or two since, in the very latest designs of some of our leading architects.

We may not look for the formation of a new style; all attempts in this direction have resulted in dismal failure, and this after all is not to be wondered at when we consider that the styles of past ages, admirable and beautiful as they are, were not created in any such way. The degree of perfection to which they were brought, was only attained after generations if not centuries of patient and laborious effort, in which the object to be gained was not novelty, but a beautiful and natural expression in the best materials at their hand, of the requirements of their age. And it is unquestionably in the same way only that any real progress can be made to-day in the true development of architecture.

DRAWING ROOM MANTEL FOR HIS HONOR, JUDGE FRINK, VERNON, B. C.—R. MACKAY FRIPP, A.R.I.B.A., ARCHITECT.

SOME WAYSIDE SKETCHES—DRAWN BY E. WILBY.

C. A. & B. COMPETITION FOR A TOWN HOUSE AND STABLE—DESIGN SUBMITTED BY "COLONIAL," (EDWARD LANGLEY, JR.) AWARDED THIRD PLACE.

Iron gas pipe was originally made up of gun barrels, lengths being formed by screwing the muzzle end of one into the breech end of another. After this, welded tubes of equal diameter and thickness were made, and the screw socket joint used to unite them. The seam was first welded, a few inches at a time, by inserting a rod within the heated tube and hammering the lap together. After this came an improvement which took the form of drawing the heated tube, arranged for butt welding, through a pair of half circular dies which forced the edges to unite.

DECORATION AND FURNITURE

CARVING.

IF we consider for a moment the present condition of the sculptor's art, as it is exemplified in the best of our modern furniture, we cannot fail to congratulate our wood carvers upon the immense advancements they have made in their industry during the past fifty years. At the time of the great exhibition the handicraft of the wood carver had sunk to the lowest art level that it is possible to conceive. Now that we have arisen from such an inartistic lethargy, it is amusing to occasionally look back into the illustrated Art Journal of the '51 Exhibition and reflect upon the many ridiculous designs that are chronicled there, as emanating from some of the then leading fashionable furnishers. If we regard such exhibits with a view of studying the contemporary carving, we can indeed discover a plethora of wonders. Sideboards carved all over with bewildering growths of convolvuli, tables with myriads of curves and cabriole legs galore, cabinets carved entirely in imitation of rustic work, and looking like glorified summer houses in suburban back gardens. Such fancies as these—unstudied, uninspired, barbarous fancies—passed current in those days for "noble and magnificent wood carving."

That kind of sculptured work represents one bad extreme—an extreme to which we have, as yet, no fear of returning. But there is an opposite extreme, viz., *forced elegance*, and to this we are quickly drifting. We lack conception, freedom and individuality in our carving, by paying too great a deference to old work, and, like the sculptors of the cinque cento, who made the same error, we are beginning to err on the side of finish and beauty, and to lose thereby the very life and soul of our labor.

The tremendous differences between the carving of our National Woodwork and the carving of to-day is evident to everybody. But, unfortunately, whereas most cultured people appreciate and admire the *old* work, they, none the less, would not accept such sculpturing from the hands of the *modern* craftsmen. Thus they do their utmost—unconsciously, no doubt—to discourage true originality. The most delightful scroll-work and vigorous crude figure carving would infallibly pall upon the taste of such people. That which many a connoisseur would rave about as *quaint* and spirited in an Elizabethan panel, would, forsooth, be blamed as barbarous if it were known to have been produced by a modern true art workman. It is this deplorable public inability to discriminate between that which is clever and original, and that which is merely a tasteful repetition, that has so effectually prevented the general introduction of the "human form divine" into our modern carved work. In an old Dutch buffet, or on a piece of Jacobean panelling, the crudest and roughest employment in the figure was regarded, in its true sense, as a quick and lasting expression of a more or less brilliant idea—not as an example of painstaking patience.

Nowadays our figure work must be perfect or it is to be condemned. And what is the result? Neither perfection or imperfection, but a worse state of affairs—the almost total absence of any attempt in our everyday furniture to introduce the figure at all. This ought not to be so. The human figure is a beautiful and essential element in our carved work, and its absence is much to be deplored. The figure gives life and sentiment to our old carved work, and all the finest epochs of our industry abound with representations of the human form.

FIG. 2.—FRENCH CARVED PANEL, PERIOD HENRY IV.

Far be it from us to advocate crudeness—the old work was crude enough in all conscience, but then the carvers of that day did the *best they knew*. Let us, therefore do likewise, and if our sentiments urge us to introduce the figure into our work, let us give the reins to our fancy, and not wait until we become Royal Academicians before we essay to attempt figure sculpturing at all. Our predecessors three hundred years ago did splendid work, with but indifferent—if any—knowledge of anatomy, and surely we, who have innumerable advantages, can excel them if we wish. But, alas! Our very advantages are our hindrances, for if we had not the means to become so clever, by studying the work of others, we should be compelled to rely on our resources and—work—instead of copy.

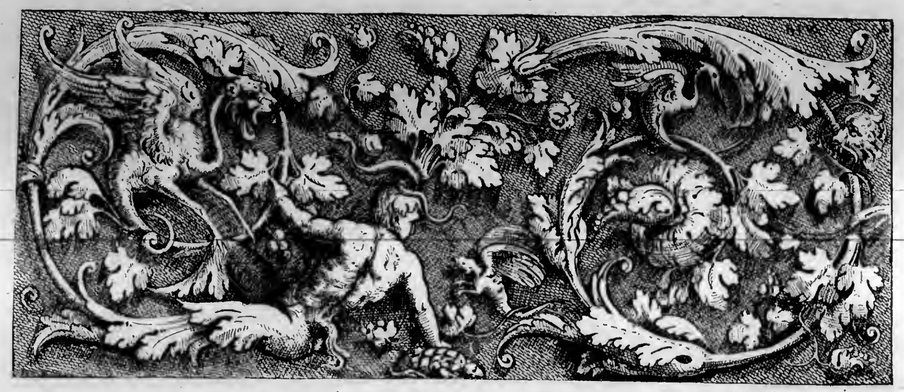

FIG. 1.—CARVED PANEL, EARLY GERMAN RENAISSANCE.

Let us glance, for instance, at the piece of old German scroll-work which is shown in fig. 1. The figure contained therein may or may not be anatomically correct—it does not matter—it is a part of the scroll, and a necessary and very interesting feature of

the panel. How much better is this than the orthodox vase would be with its everlasting acanthus scroll, even though it were Italian or Oriental London in design! For that matter, too, how unmistakably does it excel the next example that we show in fig. 2! This, however, belongs to a different period, viz., that of Henry the Fourth of France, and though it is somewhat formal design—as was usual with the work of that era—yet it is a bold and fearless effort to introduce some part of the figure at least. That life-representing head—crude and grotesque though it be—would attract the eye of an observer much more readily than the most delicately wrought but lifeless vase or patera that it would be possible to carve in its stead.

And what shall we say about the "Grotesque?" That it is a joke in art; a mere bit of fanciful bye-play? If so, it is welcome, for it cannot fail to interest us, and, may-be, amuse us. Why should not our furniture occasionally contain some embodied piece of wit? The old buffets often did; surely we stand in need of mirth in these matter-of-fact days, much more than our jovial ancestors. The sparing introduction of the grotesque into our cabinet would be a boon. It would be an easy change to effect, too, for the grotesque in carving is very much less difficult

FIG. 3.—GROTESQUE HEAD. PERIOD EARLY LOUIS XV.

to render than the perfect figure. This will be at once apparent to any one who attemps to draw a face. For example, it will be found to be extremely difficult to make a likeness, whilst it is the easiest thing imaginable to make a burlesque, simply because anything you do is a burlesque, whilst anything you do is not necessarily a likeness. So with the grotesque. Provided that we do not set ourselves to adopt any recognized school of art in this matter, we shall soon be able to produce grotesque figures with considerable facility.

The last of our sketches shows a capital study in this direction. It is French of the early Louis Quinze period, and though this is, of course, an elaborate example, it will serve to show what a degree of animation may be awakened in our work by the introduction of the figure, even though it be grotesque.

It would be well for the carver to remember, however, that there are many styles of grotesque art, and that these are extremely varied and distinctive in their several schools. These, therefore, should either be carefully studied or studiously avoided.—Furniture and Decoration.

From the budget speech of the treasurer of the Ontario Government it is learned that the expenditure on Government buildings during the last five years has been $3,167,656.

The value of new buildings for which permits were taken out in the city of Toronto in January of the present year, is $73,600, as against $56,300 for the same month last year.

Mr. Hebert, the sculptor whose design had been accepted for the Sir John A. Macdonald Statue to be erected on Parliament Square, Ottawa, has assured the Minister of Public Works that the statue will be ready for unveiling in October.

The expenditure and contracts to date on the new Legislative buildings, at Victoria, B. C., have reached the sum of $686,425, or $89,425 in excess of the limit of cost fixed by the Legislature. It seems probable that another hundred thousand dollars at least will be required to complete the buildings.

The second annual meeting of the Association of Ontario Land Surveyors was held in Toronto, a fortnight ago. The meetings, which occupied two days, were presided over by the President of the Association, Mr. Elihu Stewart, of Collingwood. A number of interesting papers were read and a pleasant time was spent at the annual dinner. The following officers were elected for the ensuing year.—President, Mr. J. Fuller, Napanee; vice-president, Mr. Gaviller, Collingwood; council, W. Chipman, T. B. Speight, V. Sankey, J. McAree, Toronto; H. J. Bowman, Berlin; J. D. Evans, Trenton; E. T. Wilkie, Almonte; H. Winter, Thornyhurst; J. W. Tyrrell, Hamilton; R. Coad, Glencoe, and W. R. Burke; Ingersoll; auditors, M. W. Hopkins, Hamilton; I. Fraynor, Dundalk; H. B. Proudfoot, Toronto; T. H. Jones, Braniford; secretary, A. J. VanNostrand, Toronto.

SOME POINTS ON BUILDING.*

BY JOS. POWER.

In taking this as a subject for a paper, I do not intend to go into any of the many points on which I may touch with any degree of elaborateness, from a scientific point of view; but merely the most salient from a constructional point, and on which so much depends; sometimes—yes often—success or failure.

In proceeding, let us suppose we are going over the requirements of the ordinary every day building. By this I mean one with which we are all familiar. We are consulted as to a building on a certain lot or site; its purpose is named. Consider well the surroundings (if of a permanent nature), the style of design best fitted for the requirements of the proposed building; and no matter for what purpose, let it speak for itself as far as practicable. By this I mean, let your design give the ordinary passer-by an idea of its use—not by ginger-bread ornament and signs, but by character and treatment. Let a "wholesale" be a plain, heavy, substantial looking building; a bank, a massive building of refined treatment; a school, plain and substantial; a collegiate, college or other public building, classic or of classic feeling, plain, neat and substantial; the public building, with broad and lofty open portal, or other entrance, simple in treatment and decoration. And, above all, let a church be a church, a model of perfection, perfect in every detail and without sham.

All this you will say is a matter of cost and seldom to be realized. Admitted, to some extent, it is; but work and advise to that end, and if then it cannot be got, do the best you can, always bearing in mind that what you do must be substantial, even if perfectly plain, and if this cannot be done with credit to yourself, better have nothing to do with it. But in most cases you can advise and prevail that more money be put in it; or the building cut down so that it may be fairly well done for the amount available.

Your design being satisfactory, see that the foundation is good—if not the rock,—that your footings are good, of large stone flags and cement, piles and steel beams if necessary. The drainage being properly provided for from a sanitary standpoint, see that it is so put in, first that the intended grade and no more is taken out, or if by chance it should, that it is made up with broken stone. Do not depend on earth, even if tamped in. Next see that the pipes to be used are of the best salt glazed, and without blemish, laid with tarred rope of sufficient size to just fill the space or difference in size between pipe and fosset, tamped well up to the shoulder of fosset. Throw your level over them to be positive that there are no low spots; then have them well blocked under with stone, to prevent rolling. They may now be cemented. Try an occasional joint by passing your knife into the cement, to know that the rope has been tamped well to the shoulder of the fosset and be most particular that they are cemented all round, especial attention being given to the under side, and if satisfactory they are now ready for filling, which, however, should not be done until the cement is dry; then fill carefully with clay well rammed to the top of the pipes.

The masonry is probably the next to require our special attention, as too many, especially when building coursing or ashlar, will give you two very poor walls where but one is required by building up the face to as much as two feet before backing it up and bonding over. This should not be allowed for at most more than one foot, and then it should be well bonded.

See that all joists have 4½ bearing, and are cut back that not more than two inches are in the wall at top edge.

When partitions are over one another, let the studs of the upper come down on the head of the lower and thus save settlement by shrinkage of joists and breakage or cracking of plaster in angles, to some extent. Where partitions meet walls have first stud well spiked to walls.

I will now pass on to the question of plumbing, one I need hardly state of the most important to the profession to-day. In laying down your system, avoid placing the pipes against outside walls, burying them in cement or behind plaster as far as possible. The soil pipe or drain should be of medium iron, well coated inside and out, with brass cleaners, whereby to remove any chance stoppage which might take place by the introduction of foreign matter, for such things will occur, even under the best of management. Introduce fresh air, if trap can be got 12 or more feet from building, or where there are no windows over, and run pipe through and well above roof, enlarged to prevent stoppage by hoar frost. Before fixtures are set, have openings plugged and system tested by filling with water. Vent all traps with pipe of same size into standing vent. Have all fixture connections made with brass and rubber, and all lead joints properly wiped and gasketed, funnels run and caulked to cast pipes. After fixtures are set, subject the whole system to a second test of either smoke or oil of peppermint. In short, have it done in the best possible way; put in no more than what is really necessary and can be done in a thoroughly sanitary and substantial way.

Mr. Blue, of the Ontario Department of Mines has lately been inquiring into the existence of clay suitable for the manufacture of vitrified brick, and reports that there are large deposits of such clay available.

* Paper read at the fifth annual convention of the Ontario Association of Architects.

WINNIPEG.

(Correspondence of the CANADIAN ARCHITECT AND BUILDER).

As the season advances rumors of "costly" and "beautiful" buildings like "the flowers that bloom in the spring" fill the air with a sweet aroma, refreshing to the souls of the weary waiting who cannot but rejoice when they see the clouds are breaking, and the shadows of hard times disappearing before the rising sun of brighter days.

Plans were prepared last year for the new St. George's church, providing for a frame building on stone foundation, but the congregation have decided to build a higher basement arranged with a large sunday school room, class, vestry and furnace rooms, and to build the superstructure of frame and brick veneer. The style to be gothic treated in a quiet manner.

The tenders of the Wesley College building were received on the 7th instant, and the amounts of some of the bulk tenders were less than $75,000 the sum appropriated for its erection. The building no doubt will be built above grade line, with Calgary stone, which is grey in color with a granite tint, very soft when first quarried, but becomes harder after being exposed to the air, is easily worked, and after allowing for the long haul, can compete successfully with our local lime stone, which is of a hard; flinty nature, and difficult to split or cut.

This country is seldom without a railroad or two looking for financial assistance from the government, and from any one else who is willing to give it. The Hudson's Bay Railroad was such a fizzle, and saddled the province with such a heavy debt, for which it has nothing to show, that the government are wisely cautious in not granting aid to any but gilt edge enterprises. The latest is he "South Eastern Railroad" to run from the city to the Lake of the Woods, with a prospect of forming a connection there with another railway to Port Arthur, thus giving a line to Lake Superior independent of the C. P. R. The promotors of the S. E. are interested in the lumber mills at Rat Portage, Keewatin, &c., and they state that should this railroad be built, all the lumber mills now at the Lake of the Woods will be removed to Winnipeg, which would be very beneficial to the city in many ways, reduce the price of lumber, and provide the market for the slabs and saw dust, which have now to be got rid of by burning in furnaces specially built for that purpose at a cost of about $5,000 each.

The Scotch pasttime, the roaring game of curling, which has been "running" this country every winter for the past four or five years, has caused buildings of a new style to spring into existence, and while they are now put together in a rough and ready manner, no doubt if the curling fever continues and the several clubs grow richer, a higher style of architecture will be demanded, which will develop and become as characteristic of the purpose as the buildings erected for other kinds of amusement.

We have here in Winnipeg, in the new Court House addition erected the past year, an excellent illustration of the old adage "great minds think alike" for the resemblance of this building to the Court House, Tacoma, W. T., is very striking, and shows how two designers miles apart can be inspired with similar ideas. The former Court House, however, is not equal to the latter either in proportion or detail, and has a squat and undignified appearance, entirely out of harmony with its surroundings, and the purpose for which it has been erected.

PUBLICATIONS.

The "Progress of the World" of the *Review of Reviews* is not confined merely to a review and discussion of current political, financial, economic and sociological events. In this department of the March number, for instance, appears a report on the geographical and scientific explorations that have recently been completed, are now being carried on, accompanied by maps and portraits of the explorers.

Whites from lead should never be used in water-color drawing. In many of the drawings by the old painters patches of black occur where the high lights were introduced. This is due to the use of white lead.

The New Massey Music Hall now in course of erection in Toronto, is to be opened with a grand musical festival on the first of June At a meeting of the architect, contractors, and the festival board, held a few days ago, it was decided that the building should be completed by the date mentioned.

CANADIAN ARCHITECT AND BUILDER.

VOL. VII.—No. 4. APRIL, 1894 PRICE 20 CENTS $2.00 PER YEAR.

THE
CANADIAN ARCHITECT AND BUILDER,
A Monthly Journal of Modern Constructive Methods.
(With a Weekly Intermediate Edition—The CANADIAN CONTRACT RECORD).

PUBLISHED ON THE THIRD THURSDAY IN EACH MONTH IN THE INTEREST OF
ARCHITECTS, CIVIL AND SANITARY ENGINEERS, PLUMBERS, DECORATORS, BUILDERS, CONTRACTORS, AND MANUFACTURERS OF AND DEALERS IN BUILDING MATERIALS AND APPLIANCES.

C. H. MORTIMER, Publisher,
Confederation Life Building, - TORONTO, CANADA.
Telephone 2362.
Branch Office: NEW YORK LIFE INSURANCE BUILDING, MONTREAL.
Bell Telephone 2299.

SUBSCRIPTIONS.
The CANADIAN ARCHITECT AND BUILDER will be mailed to any address in Canada or the United States for $2.00 per year. The price to subscribers in foreign countries, is $2.50. Subscriptions are payable in advance. The paper will be discontinued at expiration of term paid for, if so stipulated by the subscriber; but where no such understanding exists, will be continued until instructions to discontinue are received and all arrearages paid.

ADVERTISEMENTS.
Prices for advertisements sent promptly on application. Orders for advertisements should reach the office of publication not later than the 15th day of the month, and changes of advertisements not later than the 5th day of the month.

EDITORS ANNOUNCEMENTS.
Contributions of technical value to the persons in whose interests this journal is published, are cordially invited. Subscribers are also requested to forward newspaper clippings or written items of interest from their respective localities.

Subscribers who may change their address should give prompt notice of same. In doing so, give both old and new address. Notify the publisher of any irregularity in delivery of paper.

NOTICE OF REMOVAL.

Subscribers and advertisers are asked to note that on the first of May the branch office of the **CANADIAN ARCHITECT AND BUILDER** in Montreal will be removed to the New York Life Insurance Building.

THERE seems to be evidence that building in New York, which was so dull at the end of last summer that many offices closed up altogether, is becoming active again.

WE have received a letter of recent date from a contractor in Vancouver, B. C., containing some practical suggestions, and requesting that more space be given in this journal to such matters as more particularly concern the builder, naming mortars, concrete, stone setting, hoisting machinery, etc. We are now preparing some articles on these and similar lines, and in the course of the year will give our Vancouver friend and his fellow contractors reason to consider our promises in the January number well remembered.

MRS. CORNELIA COSTER, of New York, has died leaving a will which directs that the whole of her estate of a million dollars shall be applied to erecting a sepulchral monument to her memory in Woodlawn cemetery. If these are the terms of the will it will require some agility on the part of the law to sanction such a liberal interpretation as would admit of the erection of some memorial to fill a useful purpose. An exact fulfilment of the instructions would, if carried out in good taste, be a combination of conditions not usually required of architects to keep down the size of the structure without failing to spend the money on it.

THE Citizens' Advertising Committee of Toronto, who have undertaken to watch over the attractiveness of the city, have turned their attention in the right direction in resolving, at their meeting on April 7th, to endorse the immediate improvement of the island lagoons, and the construction of miniature waterways and electric launches. The island is a great natural advantage and boon to Toronto now, and one cannot pass through the lagoons without being impressed with the possibilities of further development. But, in dealing with an opportunity of this kind, so much depends upon treatment that it is to be hoped that whatever body takes the matter up will take good advice. It is only an artist who can improve on Nature by studying her effects and giving her improved opportunities to produce them. It would be easy with a crude idea conceived chiefly on paper, to make of the island a place less attractive than it is now in the beauty of its partial wildness.

THE lecture on "Current Architectural Styles" recently delivered in the hall at the School of Practical Science, Toronto, by Mr. Helliwell, and published in the CANADIAN ARCHITECT AND BUILDER last month, has received much favorable comment. Our attention has been called, however, to a peculiar omission from the examples of recent work shown on the canvas to illustrate the lecture, and the names of architects whose work is worthy of study, viz., that not one Canadian architect was mentioned nor a single view of Canadian work shown. This omission was the more noticeable from the fact that a large number of contemporary English and American architects were mentioned and recent examples of their work shown. Whatever explanation there may be to offer for the omission, we would suggest that it was hardly fair to the architects of Canada and their work. Perhaps it was owing to the lecturer's

modesty, but if so we would encourage a feeling of more pride and assurance as perfectly justifiable in regard to the work of Canadian architects, who have no reason to discount their work or allow others to do so, and no opportunity should be unused of letting this be understood, whether in Association work, private practice or a public lecture such as the one referred to.—We trust we shall have other lectures of a similar kind, in which we shall see and hear more about Canadian architects and examples of their work.

AN electric launch from the World's Fair has been introduced upon the Grand Canal at Venice and the trial has been pronounced successful. This time it cannot well be said that progress is not an improvement for, apart from the fact that the graceful movements of the electric launch will be more in harmony with the style of Venice than were the steamboats which are to be displaced, the damage to the marbles of the palaces from the contamination of the atmosphere by smoke, which Ruskin deplored, will be removed. The silent progress of the electric launches is also in harmony with the quiet of a city in which there is neither wheel or heop and in which the noise of the little steamboats was an intrusion. But, and here there is another side to the question, the steamboats on account of their necessarily large size, were confined to the Grand Canal (where in truth they have been a great comfort) but a storage battery electric launch can be built small enough to navigate the small canals, and the gondola is in danger. The gondola amply exhibited its inferiority at the World's Fair where it plied over the same ground as the electric launches. But this very inferiority may save it. To those who had seen the gondola at home and watched constantly with increasing delight the ease and rapidity with which it threads its way through the traffic on the narrow canals, the lumbering appearance it presented on the lagoons of the World's Fair was a surprise and disappointment. The apparent speed of the gondola at home turns out to be only relative to the obstruction it meets and the absolute speed of the electric launch may turn out to be too fast. It is perhaps safest to hope that it will, for we know that with the gondola the local flavour which should be present with the architecture, is safe.

ARCHITECTS in all countries will watch with a lively interest the developments in the struggle which the American Institute of Architects are making to bring about a reform in the manner of furnishing designs for United States Government buildings. With the exception of a few comparatively unimportant buildings, the designs for many years have been prepared in what might be termed the Government's machine shop for designs, known as the Supervising Architect's office. The people's money has been lavishly employed for public buildings, and the architects through their Institute show very clearly that many millions of dollars have been expended with the grossest extravagance and to no purpose but that of providing for the needs of political favorites. It is now about ten years since the A. I. A. began the present fight against the existing system. They so far succeeded that in March, 1893, a bill which had been passed by Congress was signed by the President and became law, providing for the opening of government designs to competition. For the last twelve months the A. I. A. have been making strenuous efforts to have this new law put into operation, but so far without success. The bill seems to have been passed without a mandatory clause, and its operation is largely discretionary with the Secretary of the Treasury Department. There has been a considerable amount of correspondence between the present incumbent of that office and the President of the A. I. A., in which some strong language has been used, and the result at this time looks like a deadlock between the government and the Institute as will be seen from the following letter from the Treasury Department to the President of the American Institute of Architects :

WASHINGTON, D. C., March 15th, 1894.

MR. D. T. C. BURNHAM, President A. I. A., The Rookery, Chicago, Ill.

SIR:—Your very offensive and ungentlemanly letter of the 7th instant is just received, and you are informed that this Department will have no further correspondence with you upon the subject to which it relates, or any other subject.

Very respectfully,

(signed) J. G. CARLISLE, Secretary.

The letter from MR. BURNHAM which is characterized by the Treasury Department as offensive and ungentlemanly is written in very plain language and amounts to an expression of the opinion on the part of Mr. Burnham, that while the head of the Governmental Department addressed professes to be in sympathy with the architects and favorable to the new law, he is casting about for excuses to prevent its being of any effect. It is unfortunate that the controversy has been brought to such a conclusion. It may have been injudicious of Mr. Burnham to have written so candidly, but after reading the full text of the correspondence as published in the *American Architect* of the 7th inst., we think he is quite justified in holding the opinion which he has expressed.

THERE are many buildings in our cities built just on the street line or very close to it, and so roofed that dangerous snowslides are of frequent occurrence, and at other times icicles are formed overhanging sidewalks so that if not removed they are a menace to the safety of passers by. A lesser evil, although a very disagreeable one arising from the same cause, is the falling of water from choked down pipes and overflowing eave troughs, in such quantities that people are driven from the sidewalk in places to avoid a drenching. In some cities there are regulations intended to provide for the proper disposal of roof water, but there is not sufficient care exercised for protection from snow and ice. On business streets, or any other, no part of a roof should be constructed in such shape that persons on the sidewalk below would be in any danger of a sudden fall of snow or ice. For dwelling houses the simplest prevention is to keep them far enough away from the street line to insure snow or ice from the roof falling inside private ground. If people wish to risk their own heads or those of callers, by allowing snowslides to make a target of the front steps they may be entitled to that privilege, but the line should be drawn when it comes to endangering in this manner all who are obliged or may happen to pass their property. On business streets where buildings are of considerable height and in solid blocks, showy roof architecture counts for comparatively little, and it would be in the interest of public safety if there were regulations making avalanches of snow and ice from roofs to sidewalks an impossibility. In this climate roofs sloping toward the sidewalk, with cornices and eave trough overhanging the street line, should not be allowed. Whenever there are buildings so constructed and situated that there is danger of the kind mentioned, and we are prepared to point out many such, especially in the city of Montreal, the authorities should compel owners to put suitable snow guards on roofs.

BUSINESS people in all parts of the Dominion have been greatly interested during the past few weeks in the revised schedule of customs duties, as proposed by the government at Ottawa. In many respects the changes are not as great as some would advocate, but it is probable that those who favor the strongest measures of tariff reduction, were they in power, would be obliged to proceed cautiously. Those interests connected with new building work in its various branches will not be directly affected by the new tariff except in a slight degree, as the changes are few and small. In some cases there should be changes where there are none. We will mention only as an instance of this, the item of plate glass, on which the duty is entirely too high. This is an important item among building materials, and as the duty is in no sense protective but all for revenue, the charge of 30 per cent. should be reduced by one half. We will be glad to receive any expression of opinion from interested persons relative to the duty on this or other building materials. An increasing and continued activity among the building trades must come from demands for present necessities which are comparatively easy to estimate, and from a general feeling of strong confidence in the future prosperity of the country. Expectation of new tariff legislation always creates uncertainty and interferes more or less with steady industrial progress. As the extent of cause for this feeling of uncertainty and hesitation is generally magnified to undue proportions, building interests will no doubt be enhanced by the knowledge of what the new tariff is to be, and by the greater confidence it will inspire in the stability of the business of the whole country. Let architects, contractors and all interested in building work keep up united action on any questions affecting their welfare, and which may be entitled to more consideration, legislative or otherwise. In alluding to questions involved in tariff regulations we would urge the most careful attention to the great need for a thorough change in provisions for valuing and collecting duty on imported designs and plans. So far, the result of the operations of the customs regulations in this respect appears to have differed very widely from that which the government intended. This is a matter which concerns not only the architects, but manufacturers and supply dealers as well. Canadian architects are familiar with domestic resources for materials of all kinds, and may be depended on to specify for nothing requiring importation unless in special and unavoidable instances. The relative positions of Canadian and foreign materials and manufactures is reversed when plans and specifications are prepared outside of the Dominion. The more firmly just claims in these respects are pressed the greater will be the respect and business commanded by our own people. On these lines there is still much need for thorough organization and persistent effort.

THERE are now about one hundred and sixty men at work at the new Toronto City buildings, and the number will be increased next month to over three hundred. Mr. Lennox, the architect, predicts that the building will be completed in about three years. An electric hoisting machine, operating a group of three derricks, has recently been added to the plant. As this is perhaps the first attempt to use electricity for this class of work in Canada, the result will be looked for with interest. When steam is superseded by electricity for this purpose, as it no doubt will be in a short time, the general public will appreciate the change through the absence from the streets where large building work is in progress, of the steam, smoke and noise of the old style engines.

ONTARIO ASSOCIATION OF ARCHITECTS.

The examinations of 1893 held in March resulted as follows:—

Final Examinations.—Passed, A. E. Wells.

Second Intermediate.—Passed, J. P. Mac Laren; conditioned, S. F. Smith.

First Intermediate.—Passed, C. J. Burritt, J. A. Heaman, M. White; conditioned, C. P. Band, J. L. Havill, C. P. Meredith, G. E. Stevenson.

THE ROYAL CANADIAN ACADEMY.

The annual assembly of the Royal Canadian Academy was held in Ottawa on the 30th day of March, and was largely attended by members and associates.

On the evening of the 29th the annual exhibition, held in the National Gallery, was opened by His Excellency the Governor-General, a large number of artists, their patrons and friends being present. The president, Mr. R. Harris, read a short address on the progress and aims of the academy, after which the assembly was addressed by His Excellency the Governor-General, and the exhibition declared open.

On the forenoon of the 30th March the last meeting of the Council of the academy for the year 1693-94 was held. At this meeting Messrs. D. B. Dick, of Toronto, and J. Hammond, of St. John, N.B., who had been previously elected as members of the academy, submitted their diploma pictures—Mr. Dick the perspective drawing of the new library for the University of Toronto, and Mr. Hammond an oil painting, "Herring Boats," both pictures being then on exhibition in the gallery. These were accepted, and both gentlemen were admitted to full membership. The Council also resolved to purchase several pictures then on exhibition for presentation to the National Gallery.

The following selections were made, viz., "A Song at Twilight," by F. S. Challener; J. L. Graham, "Across the Sea"; "St. Levan's Church, Cornwall," by F. M. Knowles; "A Brotles Interior," A. C. Williamson; "Bass Rocks," by J. M. Barnsley.

In the afternoon of the same day the general assembly was held, and after the reading of the reports and other routine business the meeting proceeded to the election of two painter academicians, the ballot resulting in the election of Mr. Cruikshank and Mr. Greer, of Toronto.

The following were elected as associates, namely, Franklin Brownell, Ottawa; W. E. Atkinson, Toronto; A. C. Williamson, Toronto; J. L. Graham, Montreal.

The following were elected officers for the ensuing year:

R. Harris, Montreal, president.

A. C. Hutchison, Montreal, vice-president.

J. Smith, Toronto, secretary-treasurer.

H. Langley, auditor.

The following members were declared the Council for the ensuing year: D. B. Dick, J. Hammond, O. R. Jacobi, L. R. O'Brien, T. Mower Martin, J. Griffiths, W. Raphael, T. S. Scott, A. H. Howard, F. M. Bell-Smith, A. D. Patterson, G. A. Reid.

In the evening the members and associates dined at the Russell House, and spent a very pleasant evening together.

It is generally admitted that the pictures exhibited on this occasion surpass in merit, as a whole, those of any previous exhibitions. Great care and judgment appears to have been exercised by the Hanging Committee in making suitable selections from the large number of pictures submitted for their approval. We are pleased to know that a number of the pictures have been purchased by residents of Ottawa, who have thus greatly encouraged the artists in their labors.

ILLUSTRATIONS.

ART INSTITUTE, MOUNT ALLISON LADIES' COLLEGE, SACKVILLE, N.B.—EDMUND BURKE, ARCHITECT, TORONTO.

THE art collection, consisting of some 400 canvasses and 100 pieces of statuary, to accommodate which this building is being erected, is a private collection gathered in St. John, N. B. It was given to the Mount Allison college at Sackville, on condition that suitable buildings be erected. The drawing and painting classes connected with the institution will also be housed in the same building, ample provision being made for a large number of pupils. The studios will be lighted by large windows facing north, while the galleries will be lighted entirely from the roof. The buildings will be faced with a light olive local stone. The decorative panels relieving the walls will be of terra cotta, with medallions bearing the names of noted painters and sculptors. The cost will be about $54,000.

DESIGN FOR A COUNTRY OR SUBURBAN HOUSE—BY "DEMOS."

The house is designed to face south, and it is assumed that the site is such that there is abundance of light and air on all sides. The ground floor comprises parlor, library, dining-room, and kitchen, etc. An alcove, with fireplace, forms a feature in the library, and the verandah suggested forms a valuable addition to the house. Upstairs there are four bed-rooms and a bath-room, besides a small room which would serve for sewing or dressing room. In the attic there is ample space for three bed-rooms and a lumber room.

The regularity and compactness of this plan is such that the house might be heated by a hot air furnace very cheaply and effectively.

The cost of this design in execution is estimated at from $2,500 to $3,000, varying according to local conditions.

ST. LAURENT, ROUEN, FRANCE—FROM SKETCHES BY ANDREW T. TAYLOR, A.R.I.B.A., MONTREAL.

RELIEF ORNAMENT, AND WHERE TO USE IT—ELLIOTT & SON, TORONTO.

THE BATTLE CEMENT WORKS AT THOROLD.

From a special Trade Edition of the St. Catharines Standard, we extract the following particulars concerning the above works, and their founder and present owners:—The extensive quarries covering an extent of forty-four acres, are situated on the east side of the new canal. A steam drill is kept in operation the whole year round, convenient tracks running from the quarries to the kilns, where the burning is done, and is then brought to the mill, situated on the old canal, where it is manufactured. Almost the first introduction of the cement manufactured by this firm was its use in the Victoria tubular bridge at Montreal. It was also used exclusively in the building of the old Welland canal and also in the new Welland canal. It was also extensively used in the construction of the great St. Clair tunnel between Port Huron and Sarnia. Forty hands altogether are employed. The mill is a three-story frame structure, fitted up with all the latest appliances necessary for carrying on the business, and is 150 × 50 feet in extent. The founder of the business, the late John Battle, was born in 1851, in the town of Ballymote, Sligo County, Ireland, coming to Canada in 1842. He settled in Thorold where he lived for half a century, lacking one year. He began life as a day laborer on the canal, but being industrious and frugal he soon accumulated sufficient to purchase a team, and so went on till he became one of the richest men in the district. The sons, Matthew, David, and James, are all natives of Thorold, where they are all highly respected. The latter gentlemen, is freely spoken of as the coming Conservative candidate for the House of Commons.

LEGAL DECISIONS.

William Knox versus Armstrong & Cook, real estate agents, was an action in which William Knox, architect, of Cleveland, formerly of the firm of Knox & Elliot, Toronto, sued in the Toronto Courts to recover $200 for plans supplied to the defendants. The defence set up was that the houses were to cost $3,000, and to be finished by Dec. 1st, 1890, the architects to receive 3½ per cent. The plans they prepared were for houses that would cost $3,500 or $4,000. It was necessary to get new plans and the contract set up, was recinded by the plaintiff. The defence also put in a set off to the effect that Knox owes them on an old contract to buy two lots on Spadina avenue, in 1889, and also, that they hold an unsatisfied judgment, March 20th, 1893, for $202.30 writs which are now in the sheriff's hands. The set-off was put at $318.02. Judgment was given for the defendants.

These United States patents have been granted: Hot water generator for stoves, Aleck Saunders, Goderich; wood carving machine, Aleck Saunders and John Story, Goderich.

CORRESPONDENCE.

[Letters are invited for this department on subjects relating to the building interests. To secure insertion, all communications must be accompanied by the name and address of the author, not necessarily for publication. The publisher will not assume responsibility for the opinions of correspondents.]

TORONTO INTERNATIONAL EXHIBITION, 1897.

400TH ANNIVERSARY OF THE DISCOVERY OF CANADA BY JOHN AND SEBASTIAN CABOT.

Editor CANADIAN ARCHITECT AND BUILDER.

SIR,—A suggestion has been thrown out by the Board of Trade of Toronto and by some of the daily papers concerning the above subject, but in such a spiritless way as to make it appear that the prime movers had but little anticipation of a satisfactory result being realized. It has occurred to the writer that the CANADIAN ARCHITECT AND BUILDER, with its wide circulation, is a most excellent medium for arousing sympathy, if not enthusiasm, for the project, and for helping to set the ball rolling.

There are two prime considerations in connection with any International Exposition, viz.:

1. Probable financial cost,
2. Probable financial return,

and these of course may be legitimately subdivided ad infinitum.

With respect to the cost of a prospective Canadian International Exposition—at the outset the fact of the Columbian Exhibition having cost upwards of $33 000,000 all told need not concern us in the least, either as to comparison or as to a final squelcher of the enterprise. The question simply is, are we able to produce an exhibit of creditable pretension that will pay? Let us forget for the moment the recent magnificent and unparalleled display and let us consider the approximate cost for us.

It was certainly thought in most circles that the Paris Exposition, which cost a trifle over $8,000,000, was such a tremendous success that America could scarcely hope to equal it, certainly not surpass it. But the wonder of the world was that the Columbian Exhibition not only equalled the Paris Exposition, but as far surpassed it as Paris surpassed the great exposition of 1851. Now, surely if the centre and pivot of European arts and culture considered the expenditure of $8,000,000 sufficient to startle the world, one-third of that amount would be more than creditable to a nation of five millions or so. Again, if the total expenditure of the Columbian Exposition was in round numbers say $33,000,000, then about one-twelfth part of that would be the amount in proportion to our population. And again, if Canada should expend about the same amount as was expended by Great Britain for the initial exposition of 1851, or for some of the following international expositions, it should and would be considered a very marvellous effort, and the money would more than return to us in many ways as an advertisement alone. The amounts of comparison are as follows, viz.:

One-third the cost of the Paris Exposition, '89.		$2,750,000
One half the cost of Columbian Exposition, '92.		2,750,000
Cost of London Exposition, 1851.	.....	1,450,000
" " Paris "	1855.....	1,700,000
" " London "	1892.	2,300,000
" " Paris "	1867.....	4,000,000

So that looking at either of the above examples of cost, to expend either of which amounts would be sufficient for Canada, the affair does not really assume such formidable and insuperable difficulties as one might have supposed. Take the average of the above as a basis upon which to consider what the cost of a Canadian International Exposition should be, and in round numbers the amount is $2,500,000, and even this amount is more in comparison for us than was $33,000,000 for Chicago, for we have at least a good $1,000,000 worth of buildings and land already in shape, while Chicago had to expend over $4,000,000 for works which we do not need so much to consider, i. e.,

Dredging.....	$ 600,000
Electrical plant.....	1,000,000
Docking.....	268,000
Statuary and fountain.....	725,000
Sewerage.....	925,000
Railway of Illinois Central Railway tracks and other Railway works.....	650,000
Total.....	$4,169,000

and scores of other large amounts. Can this country raise the amount required? and how? and would it be worth while so to do? are the all important questions. Off-hand then, suppose that

Toronto guarantees.....	$ 750,000
Ontario Government.....	400,000
Dominion Government.....	650,000
Other Provinces.....	250,000
Subscription in stock.....	750,000
	$2,800,000

Is there anything out of the way in such a position? The amounts are not gifts, but loans and guarantees. The stockholders would have their amounts returned in full with a dividend—the others probably in full. Supposing the cost of maintenance, premiums, judges, &c., should be say another $1,000,000—this would make a total of $3,500,000, which with our splendid nucleus at Exhibition Park, would carry us through in triumph.

Compare for a moment the extent of ground: We have more area in acres at Industrial Park than had many of the most successful International Exhibitions. The grounds at Exhibition Park may be easily added to so as to make at least 150 acres. Paris, 1867, had about 87 acres; Paris, 1878, had about 100 acres; Paris, 1889, had about 173 acres; London, 1862, Paris, 1855, London, 1857, all less than 25 acres.

Supposing an exhibition to be held in 1897, the works would be in preparation for three years, and Toronto's grant spread over that number of years, or $250,000 a year, would be no heavy burden considering the substantial benefits which would accrue to the city. It can readily be perceived that the above amount would be full enough to provide magnificent and adequate accommodation. Already the live stock buildings are perhaps unequaled on the continent, and with a small expenditure can be permanently made so. The main building ought in any event to be enlarged, and this could be done with advantage by adding T shaped ends in size about 200×125 feet. A large and commanding Liberal Arts Building should find place at the north limit of the park, in size about 800 feet by say 250 or 300 feet, if the ground would allow. If all the small buildings were removed from the space north of the present main building and placed in some other part of the grounds, large new permanent Art and Horticultural buildings could be erected there to take up all the space, or nearly so. Two large buildings ought then to be erected south of the present main building and drive having a splendid avenue or court between them of 250 feet. These large structures would be approximately—for the western one, say 450×150 feet, and the eastern one 450 feet square.

Enlarge the poultry and dog houses so as to be the finest in America, or at least three times their present capacity. Remove the annex to some other portion of the grounds, and add to it by making a part of an H shaped building and with some few other minor additions, it will readily be seen how easily and economically we may avail ourselves of our resources.

It is a matter of great importance and interest to know that 30 or 40 acres additional may at any time be added to this very attractive park at an estimated cost of from $250,000 to $300,000 by building a jetty or pier southward in continuation of Dufferin street for about 1,000 feet and continuing same at right angles eastward for 2,000 feet, then sloping the bank and partially filling in the enclosed area, making artificial lagoons and islands with fountains. The islands would preferably be parallelogram in shape, as being easily formed. The islands and piers would be shaped with cribbing, and upon two of them Marine Exhibition and a permanent Aquarium, also perhaps an Electric Building, could be advantageously placed. The layout of the grounds as suggested, with the new water front with buildings thereon, backed in the high ground with the immense new Main Building, would make a most beautiful view from the lake.

There is really no need to fight shy of such an exposition, either as to considering our inability, or cost, or extent of ground required—for it must also be borne in mind that while no doubt many foreign nations will exhibit, they will not desire to do so so largely in Canada as they did in the United States. Further ground might still be required for concessionaries, and this can also be obtained to good advantage and at small rental by taking a central strip 300 feet wide out of the property north of the railway tracks to King street, which could be let out as a Hive or Midway Baisance if you like, with of course special admission fees, thereby materially adding to the revenue. Access to this would be by a wide bridge over the railway tracks in line with the present main north drive.

The average attendance at Chicago and Paris was considerably over 100,000 per day. The smallest paying attendance for one day at Chicago was 10,701 the largest 729,203.

As Toronto is well situated in the line of travel we might well expect and count on an average attendance of at least one fifth of the Chicago Fair say 21,000 per day, which, with the receipts from the Midway Plaisance or Hive, and exhibition fees, &c., would give a much larger revenue than the calculated expenditure. And even if some extra expense was incurred and all the guarantee was not returned to the corporation and governments, save that the stockholders receive 10 in full with a dividend, what would it matter so long as the great result was a gain to Canada?

The arts and sciences would be stirred as by no other means; many millions would be brought into the country; manufacturers would be helped and more especially would the gain be great for the capital of Ontario. We have a magnificent country, a well governed Christian province, a beautiful city, and if all were well advertised who can doubt what a stimulus would be given to trade.

The result of such an exhibition would not be in the nature of a boom, with the following natural collapse, but a grand stable advertisement, much in the same way as our Industrial Exhibitions, only on a vaster scale: and following Industrial Exhibitions would be enormously helped, having so much more extensive and beautified grounds to operate in. To the painstaking Directorate of the Industrial Exhibition, the Board of Trade, and all others interested, therefore, this article is humbly submitted in the hope that the agitation may be kept up until something solid is produced.

HERBERT G. PAUL.

LETTER FROM THE SECRETARY OF THE NATIONAL ASSOCIATION OF BUILDERS.

166 Devonshire Street, Boston, Mass., April 3rd, 1894.

Editor CANADIAN ARCHITECT AND BUILDER.

DEAR SIR,—Enclosed please find list of such organizations in Canada as come within the meaning of our term "Exchange," as per my records. As to the standing and condition of these organizations I know nothing, their existence is all that comes within our statistics.

The other organizations in our records comprehend associations among architects, plumbers, plasterers, masons, carpenters, painters, lumbermen, steam and hot water fitters, electricians, etc.

I take the liberty of sending you by this mail a copy of my report to the last convention, to correct the statement in your editorial columns, clipping enclosed. You will observe by comparing your statement with my report that there is no foundation in fact upon which to base your observations. There seems to be little room for the implication that we are trying to claim affiliation from the Canadian Association. The "half dozen" you mention as being in affiliation are evidently the result of more incorrect information, as none of your exchanges are connected with our association. Yours truly,

WM. H. SAYWARD, Secretary.

[The list of Canadian organizations to which Mr. Sayward refers in his letter is as follows:

Builders, Contractors and Dealers Exchange of Hamilton, James and King William streets; secretary, William Hancock. Contractors' and Builders' Association, Hamilton, Ont., secretary, C. L. Smith, 177 West avenue north. The Builders' Exchange of London, Ont., Masonic Building; secretary, Herbert Simpson, 814 Dundas street. Montreal Contractors' Association, 99 St. James street; secretary, A. LaPierre, 107 St. Hubert street. Contractors' and Builders' Association of Ottawa, St. Andrew's Hall, Elgin street; secretary, William Northwood, 56 Rideau street. Builders' Association of Rat Portage, secretary, William R. Gerrie, Fifth and Main streets. The Builders' Exchange of Toronto, 16 Victoria street; secretary, John L. Phillips. The Builders' Exchange of Windsor, Ont., secretary, D. Willis Mason.

Several of these organizations, we regret to say, exist in name only. They should be made to form the nucleus of a strong, active and useful Dominion Association or of associations of a provincial character. EDITOR C. A. AND B.]

TORONTO BUILDERS' EXCHANGE.

25 George Street, Toronto, 30th March, 1894.

Editor CANADIAN ARCHITECT AND BUILDER.

DEAR SIR,—In your last issue there appears a letter signed "Material Man," which embodies some reflections on the *esprit de corps* of the Builders' Exchange, and as its anonymity places each of the "supply" members under the possible imputation of its authorship, a general disclaimer may not be out of order. I have written the Secretary of the Exchange calling his attention to the misstatements in the letter. Unfortunately there is no supply section in the Exchange, and this is solely due to the attitude of such persons as "Material Man," who will not frankly approach their so-styled fellow members, but assail the Exchange generally in such anonymous wails to the public as this letter in question contains. The efforts for five years past to form an association have failed owing to the anonymous violations of such conditions as could be agreed upon, and the present anonymous violation of good taste fairly represents the difficulty of combination. Let "Material Man" materialize himself and endeavor to organize his "fellow members." This he cannot do anonymously, nor outside the limits of the Exchange.

Yours sincerely,

ALBERT E. S. SMYTHE.

Editor CANADIAN ARCHITECT AND BUILDER.

SIR,—In the last issue of the ARCHITECT AND BUILDER a "Material Man" complains of not being fairly dealt with under what he terms regulations of the Builders' Exchange, and calls the attention of the Board of Directors to a matter of which I am sure they know nothing. Being a member myself, I can safely say that there are no such regulations of the Exchange, and therefore it is useless to call the Board of Directors' attention to it. If this "Material Man" is a member of the Supply Dealers' Section, why does he not complain to them or call on the secretary (who is ever courteous), and explain matters to him, and if he has been wronged it will surely be made right. If "Material Man" has such interest in the benefits of membership as he speaks of, he could have those interests better protected by making himself and his wants known at the Exchange than by writing "sore head" letters to the press, for even if such conditions as he refers to did exist the Board of Directors would want something more definite to work on than anonymous letters.

Yours truly,

T. CANNON, JR.,
95 Marion Street, Toronto.

THE COURT HOUSES AT WINNIPEG MAN., AND TACOMA, W.T.

LOMBARD STREET, WINNIPEG, MAN., March 22, 1894.

Editor CANADIAN ARCHITECT AND BUILDER.

SIR, In the March issue of your paper your Winnipeg correspondent does me infinite honor in likening my little court house in this city, costing $70,000, to the edifice in Tacoma, costing—as appears from a telegram I have this day received upwards of $300,000.

Dear me, what a wealth of detail could have been lavished on my small effort for the other $230,000! Even its alleged squattiness could have been obviated.

To quote your correspondents own words, "great minds have the same thoughts." I thank him humbly, very humbly, for his commendation, but I very much fear that, emanating as it does in this instance from an unsuccessful competitor, his opinion is deprived of much of its value.

Trusting to your courtesy in publishing the above letter, I have the honor to remain, your obedient servant,

CHAS. H. WHEELER.

[A portion of Mr. Wheeler's letter has been omitted as being foreign to the matter under discussion, and having a tendency to arouse personalities which contributors to these columns are requested to avoid.—EDITOR C. A. AND B.]

HOISTING MACHINERY.

THERE is probably no non-productive machine about a shop that earns as much, to put the matter paradoxically, writes J. H. Allen in the Illustrated Carpenter and Builder, as the crane. When we see a group of men working until every muscle is strained to the very limit of its endurance in attempting to lift a heavy casting into position on a lathe or planer, all in default of a suitable hand hoist wherewith one man could do the work in one-tenth the time with one-thousandth the actual exertion, we are disposed to look upon the proprietor of that shop as being an old fogey who is so far behind the times that it is a hopeless task for him to so much as make the attempt to catch up.

There is no shop so small, no business so poor, that should not have its complement of cranes and hoists. First of all there should be the self-sustaining hoist with a capacity equal to the heaviest of the probable requirements. When we come to the cranes they may be a simple ring in the ceiling into which the hoist is to be hooked, or the elaborate travelling crane. But for the small shop there are a multitude of simple designs that can be made at a low cost and which will serve their purposes most admirably. The most common is the straight bar, slightly curved up at the outer end, and suspended by a stay to the post, about which it swings. Old railroad iron seems to be the most suitable material for such a swinging jib. It has the advantage over the plain flat bar, in that the head and flange give it a lateral stiffness, so that it is not likely to buckle, and the unnecessary metal which it contains receives a compensation in the very low price at which it can be bought. Such a jib can be hung to a post or to the wall; the only care that need be taken is that the horizontal pull should be carefully calculated, so that it may not exceed the resistance of the wall and pull it down. It seems superfluous to call to the attention of our readers that the greater the distance between the point of attachment of the upper end of the stay and the heel of the jib, the less will be the horizontal pull on the wall.

Sometimes, however, there is no post or pillar near at hand, and the jib must be held by its own swinging post. Belts and machines may be thickly strewn around, and yet when the trolley cannot be made to serve, the swinging jib crane can usually be worked. It goes without saying that there must be some space in the floor and the ceiling above for stepping and fastening the post. So we first locate this, and then proceed to put in the longest jib that will swing over the desired arc and clear the belts. Of course, this is not long enough to pick up our work and put it where we want it; so we devise an extension jib. This can be done by building our main jib in two parts and carrying a set of rolls flush with the bottom and top, and running our extension between the two parts, and taking the upward and downward thrusts on the rollers. If they are well put up and kept level, one will be surprised at the ease with which the heavily-loaded extension can be worked in and out, and the load swung in and around the belts, that at first sight would seem to preclude all possibility of the use of a crane.

When we pass beyond the domain of the simpler tools, it is doubtful if it will pay any proprietor to construct his own hoisting tools, unless he does it to keep his men busy in a dull season and to avoid breaking into the efficiency of his working force.

If the need arises for a peculiar construction of crane for doing a special piece of work, it is probable that someone has had the same need before, and that the shop of some crane builder will have the pattern to furnish just exactly what you want. The height of hoist, the weight to be hoisted, and the power available can all be combined, and the result will be a tool especially suited to your wants.

The first travelling crane with which we had to do was one of our own designing, and of home manufacture. Its capacity was ten tons, and its span 40 ft. A railroad shop received the benefit. It was operated by hand, it moved slowly, and the general manager thought it no good. But when he learned that with this infant the time required for putting a cylinder on the planer was dropped from an hour and a half with four men to five minutes with two he looked interested. When the time of taking an engine cab from its place and putting it on the painting scaffold was cut down from three hours to twenty minutes, he ceased to gibe at our little tool made of four by six pine sticks; and when he saw a boiler come travelling down the shop far above the impediments of the floor, he owned the tool to be a handy one, and before it had been in the shop a year, he OK'd a requisition for a power tool that would lift thirty tons and cost a very pretty penny. Such is the educational influence of small things.

WATERPROOF WALLS.

A USEFUL little brocure entitled "Szerelmey and Walls," says Building News, describes the cause and cure of damp and decay in masonry. The rationale of dampness in walls is interestingly illustrated by two experiments. The proportion of water soluble in air increases with the temperature, and thus it happens that when the air is cooled, being unable to hold the water it did when it was warmer, dew or mist is formed. A damp atmosphere is really present when the air cannot hold in solution the water it contains. Then there are some substances like chloride of lime, which have a great attraction for water, and withdraw from the air the moisture it contains. Walls of absorbent materials are always damp, even in a comparatively dry air. With the varying state of the atmosphere, moisture is continually passing in and out of stone, really causing disintegration of the particles. As most of our readers know, Szerelmey's process was, after a long series of tests, and on the report of experts—amongst them Professor Faraday, Sir Roderick Murchison, Sir Charles Barry, and others—unanimously pronounced the best, and was tried on the Houses of Parliament. The ashlar walls of the Speaker's Court, to which the process was applied more than a quarter of a century ago, are in good condition. In 1875 the Szerelmey process underwent revision, and a new product, called "Szerelmay Stone Liquid No. 101" was introduced, and the older compositions are no longer made. By interposing a waterproof layer or coat between the wall and the source of damp, the water is arrested. An internal treatment is useless; so are substances which chemically combine with the masonry, or injure the stone. Ample evidence is accorded which shows that the liquid can be used for porous stone, brick, plaster, and similar walls. The stone liquid is laid on the outside of the wall with a common brush by any painter, and it sinks easily into the wall and waterproofs it. It is first stirred, then rubbed on, and Szerelmey's steel-wire brush is recommended. This stone liquid has now been in use for 18 years, and the reports appended numbering so, selected from scientific men, the clergy managers of public companies, architects, builders, and painters show the efficacy of this remedy, which has been established by the test of time.

STUDENTS' DEPARTMENT.

"CANADIAN ARCHITECT AND BUILDER" STUDENTS' COMPETITION.

SEVERAL additional designs have been received in this competition. In a number of instances, however, students have expressed dissatisfaction with the proposed method of deciding the competition, and in the case of some this objection was so strong as to prevent them from taking part. In view of this, it has been thought desirable to abandon the idea of deciding the competition by a vote of the students, in favor of the method heretofore pursued in competitions of this character. The designs submitted will therefore be referred to a commitee of three architects to be selected by the Toronto Architectural Guild, who will adjudicate upon them, and whose report thereon, together with the design that shall be given first position, will be published in the May number of this Journal.

In this connection, will the author of the design with the nom de plume "Toledo," kindly forward his name and address to this office, in order that he may be entered on our list of subscribers, and the subscription which he forwarded placed to his credit.

INTERCOMMUNICATION COLUMN.

This column is intended to afford a means of correspondence for students, builders, and all our readers desiring information they cannot otherwise obtain. Questions for which an immediate reply is required should be marked "Urgent." Names and addresses of correspondents must be sent with their communications, but these may be signed with initials or otherwise for publication.

QUESTIONS.

[14]. Would it be safe to build a chimney of a factory of sandstone? The height would be probably 200 feet. Is the stone strong enough not to crush in the lower courses?—ASPIRANT.

[15]. Could you solve for me this problem in foundation work? The site for the proposed building is half limestone and half clay. The limestone crops out at an angle, roughly, of 45°, and the clay seems to lie on the tolerably smooth side of the limestone. So far as I have been able to test the formation there does not appear to be any ledge on the limestone which would serve to hold the clay; none at any rate for a depth of 20 feet. I fear lest the clay should slide on the limestone with the weight of a building. What kind of a foundation ought I to use?—PREDICAMENT.

[16]. What is the weight of snow in a slushy condition? How much extra weight ought to be allowed for in the construction of a large flat roof in addition to the ordinary allowance for snow, where it might be difficult to get the snow off before it thaws? FROSTY.

[17]. Is there any rule, or where could I find a rule, for making a sun-dial? I think an answer published in your columns would tend to make the sun-dial more popular.—J. L. T.

[18]—1. Will you kindly let me know if there is such a thing as a durable paint by means of which brick could be given their natural whitish colour, and if so, should the brick be rubbed level before the paint is put on? 2. What paint should be used to blacken the mortar used occasionally in putting up brick buildings.—CHARLES SCHURLER, Mildmay, Ont.

ANSWERS.

[9]. "Budding Architect"—Here is a suggestion: 1. "Ferguson's Hist. of Architecture," Students' Edition; 2, "Notes on Building Construction," S. Kensington, latest edition; 3, "Building Construction," Clarke; 4, Binns' "Orthographic Projection"; 5, Paley's "Mouldings"; 6, Gwilt's "Encyclopedia."—OLD BOY.

[10]. J. B. M.—It would hardly be possible to give an answer to your question which would be certain to answer; the only way is to try one or two remedies. Coal tar, applied with a large flat brush, boiling hot, in two or three coats would probably waterproof the stone sufficiently. Boil two or three gallons at a time and set it alight when boiling. Stir continually while blazing. This will reduce the volume, and as it cools it becomes pasty, in which condition it is ready for application, but it must be boiled up for use.

[11]. My suggestion of a "reading club," or "circulating architectural journal club," or whatever it might be called, has not apparently met with a favorable reception. I should have suggested such papers as The Building News, The Builder, and such papers as are not regularly taken by the principals in our offices, but unless there is in next issue a demand for such a "club," I shall drop it. The expense need not be more than a dollar per member.—G.

[12]. A simple and thoroughly effective way of preventing the rushing of snow off a roof is the placing of iron hooks at intervals of 4 feet all over the roof in rows about 2 ft. or 3 ft. apart. These hooks hold up the snow so that it thaws gradually, and when it slips, it does so in sections, which make little noise and fall lightly.—B. X.

[8]. "Architect"—The answer given by "Architectus" to your question on "telling good cement from bad," is not satisfactory, the methods he suggests being too crude and out of date. Use cement of home manufacture, then you can get at the maker if they are not as satisfactory as represented. "Faiza" on the manufacture and use of Portland cement is a work you should read.

ANS.—[18.]—1. Do not rub the surface of brickwork before painting, except with a dry brush to remove dust or loose dirt. Good lead and linseed oil paint will be the most durable for the kind of work mentioned. The best color effect will be obtained by a practical painter mixing the tints to suit the condition of the work. This will vary with different bricks and locations: First coat with pure oil or very little color, followed by two coats in the ordinary way. 2. For mortar color the only safe thing is to use one of the best brands of the manufactured article, which may be obtained from firms whose names will be found in our advertising pages.

USEFUL HINTS.

RESIN is utilized for making the varnish used by Venetian blind manufacturers for painting their blinds. This varnish is mixed with the desired color, mostly green, and when painted gives a hard gloss enamel surface.

Radiation of heat is diffusion of heat by projection of it into right lines into space, from a body having a higher temperature than space surrounding it, or body or bodies enveloping it.

In painting houses situated at the seaside, a good deal of trouble is frequently experienced because of the action of the salt and fog upon paint, especially when it is first applied. A practical painter recommends that no paint shall be applied to work situated at the seaside until the sun is well up, in which case the wood will have had a chance of getting dry. Ochres or earth paints should not be used for priming as they are likely to be attacked by mildew, especially where boiled oil is employed as the vehicle.

Animal and vegetable substances with fine fibres, such as air, cotton, felt, wool, fur, are the slowest or worst conductors of heat, owing chiefly to their interstices being filled with air, which is a still worse conductor. Wood, sawdust, chalk, sand, stone and brick are slow or bad conductors of heat. Brick work, of either common brick or fire brick, is a bad conductor of heat. Non-conducting coverings, for preventing radiation from steam pipes, steam cylinders and steam boilers, are composed of materials which conduct heat slowly.

The painter is often credited with a great deal of the shortcomings of the carpenter, and this fact renders all contracts for painting more or less uncertain. A price may be given in that would yield a profit if the paint were applied to properly finished work, but when it is applied to wood that is knotty and sappy, or full of cracks and holes, it of course has to be made good before the paint can be put on, and this means considerable labour and expense. Such defects are more likely to occur in cheap work than in high-class work, so that in estimating on inferior jobs it is always well to leave a broad margin to cover such items.

The best method of comparing two samples of pigment together for tint and brilliance is as follows:—Procure two glazed porcelain tiles, one black for whites, pale yellows, greens, and pale colours generally; the other white for blacks and dark colours generally. A little of the sample is taken upon the point of a pallete knife and placed on the tile, and a similar quantity of the "standard" samples taken and placed close to the sample on the tile; the two heaps are then pressed by means of the knife so as to obtain a flat, smooth surface on the samples, and by holding them up nearly on a level with the eye and looking along the surface of the heaps of colour; by these means any difference in the shade of the two samples can readily be detected.

In a paper on the purification of the air in public buildings and dwellings, read before the Society of Arts by Mr. Wm. Key, an apparatus was described for filtering and washing the air. It consists of a screen formed by stretching some thousands of cords of suitable material from the ceiling to the floor of the air chamber. The cords touch each other and are interlaced horizontally with copper wires, which are drawn tight to give the screen a flat surface, so that it has the appearance of coarse cloth. Air passing through is broken up into minute streams, and is washed free from impurities by water trickling down the cords. Experiments showed that not a particle of the densest fog passed through the screen, the air being filtered "bright and clear, perfectly sweet, and free from odor." Dust particles were not so perfectly removed, but it was noticed that after removal of fog, the air was so much brighter and clearer than usual as to suggest that the artificial production of fog might ensure the complete removal of very minute dust particles.—Scientific American.

The effect of different beds in making compression tests of stone has been investigated by Prof. Malverd A. Howe, of the Rose Polytechnic Institute. Cast iron, soft pine, sole leather, sheet lead, and tar board were tried, and the results indicate that to obtain the best idea of the comparative strength of stones, the specimens should be cut with perfectly parallel plane ends and tested between parallel iron or steel plates. As this calls for considerable labor and expense, other materials may be used, but the results were not accurate. Sheet lead seems to distribute the pressure well, but lowers the strength, as registered, by an undetermined amount, depending on the structure of the specimen. Pine splits so easily as to be undesirable. Tar board was found to distribute the pressure very well, but raises the registered strength of the specimen; in spite of this defect Professor Howe believes it to be the most reliable bed for commercial tests of the five materials examined. This conclusion is based upon but 80 experiments, but is considered warranted by the uniformity of results and conditions.

CHARACTERISTICS OF VARIOUS WOODS.—It has long been known that certain woods possessed capabilities fitting them for particular classes of work; but a concise table of collected data on this point will be found useful. The woods noted for elasticity are: Ash, hickory, hazel, lancewood, chestnut (small), yew, snakewood. Elasticity and toughness: Oak, beech, elm, lignum vitæ, walnut, hornbeam. Even grain (for carving or engraving): Pear, pine, box, limetree. Durability (in dry works): Cedar, oak, poplar, yellow pine, chestnut. Furniture: Beech, birch, cedar, cherry, pine, whitewood. Best Furniture: Amboyna, black ebony, mahogany, cherry, maple, walnut, oak, rosewood, satinwood, sandalwood, chestnut, cedar, tulipwood, zebrawood, ebony. Building (ship-building): Cedar, pine (deal), fir, larch, elm, oak, locust, teak. Wet construction (as piles, foundations, thames, etc.): Elm, alder, beech, oak, plane-tree, white cedar. House building: Pine, oak, whitewood, chestnut, ash, spruce, sycamore. Machinery and millwork (frames): Ash, beech, birch, pine, elm, oak. Rollers, etc.: Box, lignum vitæ, mahogany. Teeth of wheels: Crab-tree, hornbeam, locust. Foundry patterns: Alder, pine, mahogany.—Illustrated Carpenter and Builder.

The death is announced of Mr. Thomas Cuthbertson, the well-known architect, of Woodstock, Ont., which occurred about a fortnight ago.

WINNIPEG.

(Correspondence of the CANADIAN ARCHITECT AND BUILDER.)

The Provincial Government have decided to erect a new Court House at Portage la Prairie, and build an addition to the jail there. Mr. George Browne, architect, has charge of the work. The buildings are to be of local brick, on stone foundation, with trimmings of Calgary stone, and heated with hot water. The present court house was erected in the early days, and is now in a very dilapidated condition as well as inconveniently situated, being at the extreme east end of the town, some distance from the business portion, owing to the latter having moved west after the fire swept the then business centre a few years since.

Building promises to be brisk in the "Portage" this summer, for besides the above buildings, there are to be erected two brick school buildings, a large store for the Hudson's Bay Company, and a post office as well as several residences. Mr. Smith Curtis is at the head of an excellent scheme for widening the water power of the Assiniboine river, and turning the useless slough into a useful lake which would make the town a favorite summer resort, and provide a delightful place of retreat for the weary worker.

The fine weather we have been enjoying the last week or two, has helped to stimulate one another into good works, or at least to project them, for parties who propose building, are now rushing their plans forward, in order to have the contracts let before there is a rise in prices, which is supposed will take place as soon as the season opens up.

If an arrangement can be made with the Dominion Government for the support and education of the deaf and dumb, of the Territories, they will be brought there and the deaf and dumb building will be enlarged to accommodate them, an appropriation of $10,000 having been made for that purpose at the last session of the Provincial Legislature.

MONTREAL.

(Correspondence of the CANADIAN ARCHITECT AND BUILDER.)

Messrs. Dunlop & Heriot, architects, have designed for St George's church in this city a new and graceful tower to be over 100 feet high and in the perpendicular style, detail in the early decorated style to which the church belongs.

The Hon. Mr. Nantel, Minister of Public Works for this province has instituted an action for $10,000 libel against a weekly paper of Quebec which insinuated that the expenses of his present trip to the Holy Land were being defrayed by the contractors of the Montreal Court House.

It was recently enacted by the Legislature of this province that every advocate, notary, physician, dentist, land surveyor, civil engineer, veterinary surgeon, artist, painter, musician, sculptor, and architect, practising his profession within the limits of the province, shall pay an annual tax, the amount whereof shall be that indicated in the following tariff:—If he has his principal office or place where he exercises his profession: *a*. In the city of Montreal or Quebec, six per cent. on the rent or annual value of such office or place; *b*. In any other city or town, $6; *c*. In any other municipality, $3.

The following requirements for specifications for concealed incandescent wiring in houses under construction have been adopted by the Montreal Electric Club, and are recommended for use by Canadian architects:—

1. All wire used must be rubber covered and equal to either Habirshaw, Grimshaw or Bishop.
2. No gauge smaller than No. 16 B. & S. shall be allowed to be used.
3. Wire for 52 volt current, on two wire principle, loss not to exceed two per cent.
4. All joints to be well made and properly soldered, and shellaced, covered with a layer of rubber tape, also with an outer covering of good black friction tape.
5. Place necessary cut outs as required by Board of Fire Underwriters rules, the same to be on slate or porcelain bases and double pole.
6. Where wires pass through walls and floors they are to be protected by an extra covering in the shape of a durable and moisture proof insulating material, excepting soft rubber tubing, equal in thickness to the insulation on the wire.
7. Where wires run along ceilings and walls, they must be kept at least two and one-half inches apart; where passing through holes in the walls and flooring, each wire must have a distinct hole for itself.
8. All speaking tubes, gas pipes, and metallic substances of like nature are to be avoided, but where it is necessary to cross same, the wires must be bridged over with wood or hard rubber tubing. If the pipe is for hot water or steam, an air space of at least 4 in. is to be allowed between wires and pipes. All wires crossing water pipes should pass over said pipes if possible or be protected from drip.
9. Outlets for single pole switches may be left where there are not more than 8 amperes to be controlled; where there are more than this quantity the outlets must be arranged for double-poled switches.
10. No staples or metallic fastenings will be allowed for holding wires in place.
11. Outlets must be taped when passing through plaster.

Place outlets as follows:

The Electric Club in a circular to architects, add the following by way of suggestion:—

We might also suggest that electric work (even electric bells) be placed on a separate tender. This will not stop any reputable plumber, who does electric work, from tendering on either electric light or electric bell wiring, whilst it will stop subletting the electric bell work or electric light work, thus causing a double profit to be added to same by those plumbers who do not. The above remark we have thought in season seeing that it is customary with some architects to place electric bell and annunciator work, and sometimes electric light wiring, even, in the regular plumbers' specifications along with gas and steam fitting.

PUBLICATIONS.

"The Progress of the World" of the April Review of Reviews contains a timely discussion of the question why the English game of politics is more exciting than the American game. Other topics are, the Seigniorage bill, filibustering in Congress, the outlook for bimetallism, the Wilson bill in the Senate, the Senate report on Hawaii, the triumph of the Brazilian republic, the fight against the House of Lords, the Russo-German commercial treaty, the death of Louis Kossuth, and many matters of international interest.

A siccative material is any compound which, added to linseed oil, either hot or cold, hastens its drying qualities, which are naturally slow, and renders its use in painting and varnishing practicable and efficient. Liquid drier is simply a concentrated boiled oil. The most reliable form of drier is a compound of bases having the property of several oxides and series of salts.

QUEBEC MECHANICS' LIEN ACT.

On the 8th of January last the Legislature of the Province of Quebec gave its assent to the following amendments to Chapter 46 of 57 Victoria, relating to the privileges of builders, labourers, workmen and suppliers of materials, which are here printed for the information of contractors doing business in Quebec.—

1. Paragraph 7 of article 2069 of the Civil Code is replaced by the following:

"7. The claim of the labourer, workman, supplier of building materials and builder (chief contractor), subject to the provisions of articles 2013."

2. Article 2013 of the said Code is replaced by the following articles:

"2013. The labourer, workman, supplier of building materials and the builder (chief contractor) have a right of preference upon immovables, to the amount of the increased value given by the work done or materials furnished, over any other creditor except the creditor having one of the privileges mentioned in the first six paragraphs of article 2009 (1) and shall further have a preference over all chirographic creditors upon the said immovables.

"2013*a*. The privilege of the labourer, workman, supplier of the materials and builder (chief contractor) ranks as follows:—

1. The labourer;
2. The workman;
3. The supplier;
4. The chief contractor.

"2013*b*. The right of preference or privilege upon the immovable exists as follows:

1. Without the registration of the claims in favor of the debt due the labourer, workman, supplier of materials and the builder (chief contractor), during the whole time they are occupied at the work or while such work lasts, as the case may be; and with registration, provided it be registered within the thirty days following the completion or the cessation of the work;

2. But such right of preference or privilege shall exist only for two years from the date of the registration, unless a suit be taken in the interval, or unless a longer delay for payment has been stipulated in the contract.

"2013*c*. The preservation of the privilege is subject to the following conditions:

1. The labourer and workman must give notice, in writing, or verbally before a witness, to the proprietor of the immovable, that they have not been paid for their work, for each term of payment due.

Such notice may be given by one of the employees in the name of all the labourers or workmen who are not paid.

2. The supplier of materials shall, before delivery of the materials give notice in writing to the proprietor of the immovable, of the contracts made by him for the delivery of materials, and mention the cost thereof and the immovable for which they are intended.

3. The sub-contractor shall, within eight days from the signing of the contracts, also inform the proprietor or the *bailleur de fonds*, of either of them, as the case may be, or his agents, of the contracts he has entered into with the chief contractor.

"2013*d*. In order to meet the privileged claims of the labourer, workman and supplier of materials, the proprietor of the immovable may retain an amount equal to that which he has paid or will be called upon to pay, according to the notices he has received, as long as such claims remain unpaid.

"2013*e*. In the event of a difference of opinion between the creditor and the debtor with respect to the amount due, the creditor shall, without delay, inform the proprietor of the immovable, by means of a notice which shall also mention the name of the creditor, the name of the debtor, the amount claimed and the nature of the claim.

The proprietor retains the amount in dispute until notified of an amicable settlement or a judicial decision."

3. Article 2103 of the said Code is replaced by the following articles:

"2103. The privilege of the persons mentioned in article 2013 dates, in the cases mentioned in paragraph 1 of the article 2013*b*, only from the registration, within the proper delay, at the registry office of the division in which is situated the immovable affected by the inscription of a notice or memorial drawn up according to form A, with a deposition of the creditors sworn to before a justice of the peace or a commissioner of the Superior Court, setting forth the nature and the amount of the claim and describing the immovable so affected.

2. In registering such memorial, it is sufficient to mention, opposite the official number of the cadastre which describes the immovable, if the cadastre be deposited, or opposite the title of the registered deed, if the cadastre be not yet deposited, the name of the claimant and the amount due at the time the memorial is filed.

3. The memorial shall be made out in duplicate, one copy of which shall remain in the archives of the registry office and the other be delivered to the creditor with the registrar's certificate thereon.

4. The creditor shall, within three days from the registration of the memorial, give a written notice to the proprietor of the immovable, or to his agent if he cannot be found.

"2103*a*. The sale to a third party by the proprietor of the immovable or his agents, or the payment of the whole or a portion of the contract price, cannot in any way affect the claims of persons who have a privilege under article 2013, and who have complied with the requirements of articles 2013*a*, 2013*b*, 2013*c* and 2013 of this Code."

4. All articles of the Civil Code inconsistent with the provisions of the Act are repealed.

FORM A.

Form of notice or memorial.

A. B. (*name and residence of claimant*), do hereby declare that I have worked upon the immovable of (*name of the proprietor*), at the following works (*nature of the works*), (or I have supplied, *if he be a supplier, etc., as the case may be*) since (*give the date*); that the amount due me is (*amount of the claim*); that the immovable on which I have worked is described as follows: (*Number of cadastre or description by metes and bonds as much as possible.*)

Sworn before me, this day of 18 | (*Signature*) A. B.

C. D., Justice of the Peace.

(1) PRIVILEGES ARTICLE 2009 of the CIVIL CODE.

1o. Law costs and the expenses incurred for the common interest of the creditors.
2o. Funeral expenses, such as declared in article 2003 (that is limited to the station and means of the deceased) when the proceeds of the movable property have not proved sufficient to pay them.
3o. The expenses of the last illness, such as declared in article 2003, and subject to the same restriction as funeral expenses.
4o. The expenses of tilling and sowing.
5o. Assessments and rates.
6o. Seignorial dues.

THE HARMONY AND FUNCTIONS OF COLOUR IN ART. *

By Andrew T. Taylor, A.R.I.B.A.

The love of colour is natural to man. All savage and barbarous peoples have in common the love of bright colors. Pioneer traders and explorers in Africa and in the South Seas, knowing this, always take care to supply themselves with gaudy calicos and bright coloured beads for purposes of gifts, or of barter. A child is attracted by colour perhaps more quickly than by anything else. It is only as we emerge out of childhood whether of the individual or of the nation we become more fastidious in our harmonies of colours.

Imagine if you can all colour taken out of the world, we would still have the same beautiful shapes which are lavishly strewn around us in mountain and valley, in tree and rock, in wild flower and grass, in bird and fish and animal, but with what a difference—the light would have died out of them; the whole surface of nature would be neutral tint—an ashen grey. Nature would come out in old Quaker costume. Our colour sense rejoices in the polychromatic feast continually spread before it, and there is no purer enjoyment than the contemplation of the rich colouring of nature, ever varied and ever varying with the changing year.

Do we ever stay to enquire why nature is so lavish with her beautiful colours? No doubt the colours of many of the flowers have their useful purpose, such as attracting insects and bees and humming birds, who in the beautiful ordering of nature are thus unknowingly working out its great laws. And we know that at certain periods the plumage of some birds assumes a brighter and more gorgeous hue; but after allowing for all this there is infinite beauty and variety of colour which we can only accept gratefully as the creation of a Beneficient Giver to minister to our pleasure and enjoyment and gratify and delight the love implanted in us for beautiful things. There are people so utilitarian as not even to allow this, and who would fain argue that every variety of tint and shade in leaf and blade and mountain side has its direct use, and only to be justified on that ground.

As *Punch* jocularly but with great truth asks—"Are we to deny the existence of any good that is not visible, that is not tangible, that cannot be measured with a tape or weighed in scales?" and goes on to say—"There are people who would find the universe none the poorer had Praxiteles carved nothing more immortal than an occasional cold fowl; had Homer swept his lyre, not in commemoration of the fall of ancient Troy, but to celebrate the rise of a new soap; and had Titian lavished all his wealth of glowing colour and gorgeous hues upon the unretentive surface of some suburban pavement." It is not for such people, however, that nature spreads her colours upon her palette, but for those who having beauty in their own natures, feel a responsive chord vibrating to that of nature around.

It seems prosaic and callous to analyze the colours and tints instead of being content to enjoy them as we see them in nature, or in some great picture, but we shall be able more intelligently to enjoy them if we understand something of the principles which underlie the harmonies of the colours, for nature has rules for her colourings as well as for her economy, and we shall be able in the measure in which we understand them, to reproduce in our homes and our own handiwork something of the same gratification and pleasing emotions which we feel in nature—often without understanding the reason for it. This knowledge I need not say has been very much neglected, with the result that we all deplore, but which might have been expected, viz., in harmonious arrangements of colour in dress, home decorations and in all our surroundings. It will be my endeavor to state some of the elementary principles underlying harmony of colour, and if time permits, attempt to show their application to our general art.

The source of all colour is light acting upon the retina of the eye; without light we can have no colour. White light was once supposed to be a primary element, but as you all know, it has long been known to be composed of a number of colours which cannot be divided into fewer colours than three, and these are therefore called the three primary colours. This was first clearly shown by Sir Isaac Newton in his solar spectrum. The reason for it may be stated thus: Although light travels with immense rapidity, being at about the speed of about 186,000 miles in a second, yet a sensible time is occupied in this transmission, as we know that light takes about 8½ minutes to come from the sun to our earth. The velocity of light is also affected by the media through which it comes. For example, a beam of light made to pass through a glass prism is retarded by the different thicknesses of the glass, so that if the light, after passing through the prism be thrown on a white screen or even onto any object, a variety of colours will be obtained.

The vibrations composing white light are unequal and posses different degrees of energy; the red and orange are the most powerful, the green and yellow come next, and the blue and violet are the weakest of all. These coming through the medium of the atmosphere, keep together, and even passing through ordinary glass are not much affected, but in passing through a prism the weaker vibrations are more deflected out of their course than the others, while the stronger ones take the nearest way to their straight course; thus red and orange are the least refrangible rays, then come yellow and green, and blue and violet are the most refrangible. It has been found that, for example, violet light is caused by vibrations of about the 57,000 part of an inch long; as these vibrations are reduced the violet changes to a bluer light and soon to green, and then yellow and orange, until we get the uncompromising red with vibrations of about only the 39,000 part of an inch. So that, to speak more scientifically, light is simply vibrations of different intensity, and acting upon the retina of the eye, produces sensations which we call colours. The different sets of nerves of the retina respond to certain vibrations of light and produce the sensation of red, or yellow or blue. But that is not all. Natural bodies have the power to select and absorb certain of the vibrations and to reject the others; these rejected vibrations are received upon the retina and produce the colour which we ascribe to the object. There is really no original color in any object.

The splendid colors of the feathers of certain birds, as of the peacock, the lustre of beetles' wings, the sheen of mother of-pearl and certain precious stones, are only due in a very few instances to any actual coloring matter in themselves; in nearly all cases they are caused by the reflection and refraction of the rays, owing to minute inequalities and folds and marks on the surface of the feathers or shells. This has been imitated by Japanese metal workers who employ the same methods to get iridescence and variety of hue in their articles made of iron and copper. It would be going out of the scope of this paper to pursue this part of the subject further, but I have tried to indicate enough to enable you to understand what I have now to say.

Sir David Brewster's arrangement of the colors has been long accepted as correct, viz., red, blue and yellow as the three primary colours, but of late Winsch's and Young's theory has been taken up, adopted and advocated by men of acknowledged position in physics, such as Helmholtz, Maxwell and Rood. Even they are not agreed as to the exact hues, each varying slightly, but roughly speaking it may be said that they agree on adopting red, green and violet-blue as the three primaries. There is, however, in this selection a measure of arbitrariness, and there must be a certain liberty allowed. But to understand this aright, a distinction must be made between lights and pigments; experimenting with rays of light they found that blue and yellow lights do not produce green when mixed, but they also found that blue and yellow pigments when mixed *do* produce green. How is this? In this way: There is no actual colour in the pigments, their colour arises from the absorption of certain rays. What they do *not* absorb gives the colour, it is those rays we see by reflection. In Young's theory they recognize three primary colour *sensations*; in Brewster's we have three primary *colours*,—a very important distinction. For a purely theoretic study of the subject of colour we should adopt Young's theory, but for our purpose and for practical study, we will follow Brewster's theory. These rays, red, blue and yellow, cannot be further divided, or as it is called decomposed. These colours or rays, however, are not equally strong. If you wish to harmonize so that each is neutralized or destroyed, you must take them in the proportion of *three* parts of yellow, *five* of red, *eight* of blue, making together sixteen parts. These three primaries in the state of transient colours, such as for example in the colours of the prism, when recomposed, will produce white light. Any *two* of these colours mixed in their proportions, give what we call secondary colours. For example, three yellow and five red will produce orange, and orange will harmonize with blue, the remaining primary colour, in the proportion of 8, making 16. Also five red and eight blue will produce purple, which will harmonize with the remaining primary colour, yellow, in the proportion of 3, making 16.

Also eight blue and three yellow will produce *green* which will harmonize with the remaining primary red in the proportion of five, making 16.

Now we have got red, blue, yellow, the three primary colours, and orange, purple and green, the three secondary colours, and we got the secondary colours by mixing two of the primary colours together.

To obtain the *tertiary* colours we proceed to mix two of the secondary colours together. For example, orange and purple will produce the tertiary colour *Russet-brown*, and will harmonize with the remaining secondary green in the proportion of 21 russet to 11 green.

Also purple and green will produce the tertiary colour *olive*, and will harmonize with orange in the proportion of 24 olive to 8 orange.

Also green and orange will produce the tertiary colour *citrine*, and will harmonize with the remaining secondary, viz., purple, in the proportion of 19 citrine to 13 purple.

We have thus got the primaries, the secondaries and the tertiaries, and you will observe that as we get to the tertiaries, the tendency is to destroy the strength of the colour, and to make them neutral, because the whole three primaries are in them.

Every colour has got its complimentary colour, that is its opposite contrasting colour, which will make it look best and most agreeable to the eye, and it is very important to know the complimentary color of each. How shall we know that? Very easily. Bear in mind that any scheme of colour is never satisfactory that has not got all the three primaries in one form or other, and this will enable you to know what is the complimentary colour or shade to any colour you may have.

Thus, take yellow, the brighest of all colours, and nearest light—to get a harmonious scheme of colour you want the other two primaries; these are red and blue, which make *purple*; and purple, therefore, is the complimentary of yellow, and is also almost the darkest of hues,—the contrast therefore is as light to dark.

Again take red, which is a warm, exciting, hot colour, the other two primaries are blue and yellow. These mixed together make *green*, and green is the complimentary colour of red, and it is also the most soothing and quieting to the eye,—the contrast is therefore between exciting and quieting. We find this in the red flowers and green leaves and red fruits and green foliage.

Again take *blue*, which is the coldest colour—the other two primaries are red and yellow, which mixed together make *orange*, and orange is the complimentary colour of blue, and it is also the warmest colour. The contrast is between coldness and warmth. We find this in nature in the blue sky and the warm sunshine. You can prove this by a simple experiment. Take a piece of white paper and put a red spot in the middle, gaze fixedly at it for a minute in a good strong sunlight; remove or cover the red spot and you will see a green spot instead of the red, the green being the complimentary colour of the red, being made of the other two primary colours, blue and yellow.

The reason for this curious phenomenon is this: The eye tires quickly of one colour. The particular nerves excited by that colour become wearied and fatigued, and in the ratio in which this happens, so the other nerves become correspondingly excited towards the complimentary colour to that which fatigued the other nerves, and you see as I have described. As the wearied nerves recover their tone the hues blend into their proper relations again. You may take a similar experiment with the sun when low down in the sky—say at sunset—after gazing fixedly at it, you will see a purple disc, purple being the combination of red and blue, the remaining primaries after the yellow, and so with the other colors.

You will please bear in mind that each shade of colour has its complimentary, and as there are hundreds of shades, I can only give you the general principle on which the harmony of colours depends.

In making these experiments and mixing colours and shades, which I hope you will all do for yourselves, you will please bear in mind that the colours you deal with are not pure, and that it is only an approximation to the pureness that you can get, so that your experiments can never be absolutely correct, but you will get something near to it. The theory is, of course, built on pure colours as in the spectrum.

I need not say that you will hear colors spoken of as warm or cold, and when you hear this you will know that all orange and yellows and reds are warm, and all blues, grays and the blue greens are cold, and the colours become cool as they have blue in them, and warm as they have red or yellow.

Now we will go a little further. There is what is called simultaneous contrasts of colour and may be either *contrast of depth* or intensity, as when two tints are placed together, and the *contrast of hue*, making an apparent change of colour when certain shades are put beside it. This arises from the fact that all colored bodies reflect a certain amount of their complimentary rays, and also of white light. For example, take two patterns of the same colour, the one light and the other dark, and put them together, the one will appear lighter and the other darker by contrast; and if you take two different colours of unequal intensity and put them together, you will find not only one will be lighter and the other darker, but each will be slightly affected by the complimentary colour of the other. That is the reason that colours often look different when placed on a wall with other colours than they did on the sample. You will also find that by putting two complimentary colours together they will both look fresher and richer and give the most agreeable impression; on the other hand, if you put colours which are not complimentary together, both are injured and hurt, and a disagreeable impression is felt. For example, take red and green—both look their best, but if you put red and orange or red and purple, both will be injured.

(To be Continued.)

* Paper read at a meeting of resident members of the Province of Quebec Association of Architects, at Montreal.

A TEST OF FIRE DOORS.

H. Clarkson, of Topeka, Kan., has been experimenting with fire doors. The following is an account of the tests made:

"The shutters experimented on were of small size and consisted of wood covered with tin and other light metal. Two thicknesses of mortised boards with the grain of the wood in the two sections placed at right angles were used for the interior and were nailed tightly together. Several kinds of covering were tried. One was a single thickness of black iron, the second two thicknesses of galvanized iron, the third one thickness of tin, the fourth two thicknesses of tin, the fifth two thicknesses of tin lined with asbestos, and sixth a single thickness of tin lined with asbestos.

"The outer coverings were all made air-tight and the nail heads covered. The sample shutters were put into an improvised furnace and subjected to a heat of 1,600 degrees for forty-five minutes with very good results. All of the samples came out in good shape except one, in which a layer of metal was placed between the wooden layers inside. The edges and corners of the others were in perfect form and were not warped out of shape. The wood inside, of course, was turned to a perfect charcoal, but as it could get no air did not burn up.

"The heat to which the samples were subjected is hotter than shutters would receive on building, for there it would only be on one side.

"The samples were afterward sawed in two and it was found that the tin lined with asbestos was probably the most satisfactory of all. One great advantage, besides its not warping, in this kind of shutter is that in case of fire within, the tin and wood can be cut through with an axe. Later experiments will probably be made with full-sized shutters."

TRANSVERSE STRENGTH OF BRICK MASONRY.

THE following abstract of a series of experiments on the transverse strength of brick masonry made by Messrs. M. A. Earl and A. B. Loomis, of the engineering department of the University of Illinois, and published in a recent number of the "Technograph," a student's publication, is, therefore, of considerable interest.

In these experiments eight beams and two piers were broken. The beams were broken as simple beams with a concentrated load at the center, and the piers were first broken as cantilever beams and afterward as simple beams. The conditions and results of the several tests were as follows:

Beam No. 1 was built of two thicknesses of stretchers like an ordinary double wall, with the third course from the bottom headers. There was also a bond at the ends. Its depth was 14.7 ins. and the distance between the supports 43.75 ins. Its age when broken was 28 days. The beam failed at the center, about as much from lack of cohesion in the mortar as from mortar separating from the brick. This statement will apply to all the beams. One brick was broken by tension. Since the weight of the beam, 350 lbs., acts as a uniform load, its effect is the same as 175 lbs. at the center. Hence the breaking load = 1,652 + 175 = 1,827 lbs. The modulus of rupture, therefore,

$$\frac{6\,M}{d^2\,b} = \frac{6 \times 1827 \times 43.5}{4 \times 7.75 \times 217.56} = 70.7.$$

Pier No. 1 was pulled over as a cantilever beam. Age 28 days. Failed by mortar separating from brick. Weight of pier, 295 lbs. Force to break, 205 lbs. applied 42.5 ins. from joint of rupture. Maximum tension per sq. in.

$$\frac{M}{I} \cdot \frac{W}{S} = \frac{205 \times 42.5 \times 11\frac{1}{2}}{2 \times 1\frac{1}{2} \times 7\frac{1}{2}(11\frac{1}{2})^2} \cdot \frac{295}{7\frac{1}{2} \times 11\frac{1}{2}} = 49.3$$

Beam No. 2 consisted of pier No. 1 broken as a simple beam. Length between supports, 43 ins.; depth, 7½ ins.; width, 11½ ins. Weight, 295 lbs. Load to break; concentrated, 160 lbs.; weight of beam considered at center, 148 lbs.

$$S = \frac{6\,M}{b\,d^2} = \frac{6 \times 308 \times 43}{4 \times 11\frac{1}{2} \times (7\frac{1}{2})^2} = 30.7 \text{ lbs. per sq. in.}$$

In this case, and also in the pier, the unit stress is necessarily small, since there is no interlocking action of the brick as in an ordinary beam.

Beam No. 3 was built essentially the same as No. 1. Age 56 days. Length 4 ft.; depth 4¾ in.; width 7¾ ins.; distance between supports, 43 ins. Weight 350 lbs. Concentrated load, 3,273 lbs. The beam did not fail, thus showing a strength of at least 117.2 lbs. per sq. in.

It was then turned on the flat side and broken with a concentrated loud of 1,507 lbs., or 122.4 lbs. per sq. in.

Beam No. 4.—Age, 49 days; depth and width consisted of the same number of courses as No. 1; depth, 15 in.; distance between centers, 122 ins.; width 7¾ ins.; weight, 1,000 lbs. Five bricks broke when the beam failed. When this beam was broken deflections were taken at the center by means of a level and rod. These are given in the following table:

Deflections, in.	Differences.	Weights applied.
0.00	0.00	0.00
0.05	0.05	....
0.96	0.01	+ 200 lbs.
0.07	0.01	+ 400 "
0.11	0.04	+ 600 "
0.17	0.06	+ 800 "
0.23	0.06	+ 1,000 "
	Beam broke.....	+ 1,224 "

At the vertical joints the mortar separated from brick; at the horizontal joints the mortar failed in cohesion. Strain, 181 lbs. per sq. in.

Beam No. 5.—Depth, 15 in.; width, 7¾ ins.; distance between supports, 55 ins.; weight 500 lbs.; age 61 days; breaking load applied at center, 1,678 lbs. Strain, 91.2 lbs. per sq. inch.

Beam No. 6.—Width and depth the same as No. 5; distance between supports, 55 in.; age, 62 days; breaking load, 2,070 lbs.; weight of beam, 500 lbs. Strain, 115.5 lbs. per sq. in.

Beam No. 7.—Age, 62 days; distance between supports, 44 ins.; depth, 7¾ ins.; width, 3½ ins.; center load, 378 lbs.; weight of beam, 80 lbs.; strain, 153.8 lbs. per sq. in. The beam was not broken.

Beam No. 8.—Two courses high and two courses wide; depth, 4¾ ins.; width, 7½ ins.; distance between supports, 45 ins.; weight of beam, 125 lbs.; breaking load, 200 lbs.; age, 62 days; strain, 112.7 lbs. per sq. in.

Beam No. 9.—Lower section as No. 2; built as piers; distance between supports, 37 ins.; width, 7½ ins.; depth, 11½ ins.; age, 62 days; weight of beam, 270 lbs.; center load, 970 lbs.; strain, 54.3 lbs. per sq. in.

Beam No. 10.—Age, 35 days; distance between supports, 6 ft.; depth, 14 ins.; width, 8 ins.; center load, 1000 lbs.; weight of beam, 670 lbs.; strain, 99 lbs. per sq. in.

A summary of the results of the tests giving the modulus of rupture for the several beams is given in the following table;

No of beam.	Age. days.	Strength of mortar at that age in lbs. per sq. in.	Modulus of rupture of beam in lbs. per sq. in.	Remarks.
3	56	50	117.2 to 122.4	Broken sidewise
4	49	48	181	Mortar 1 to 2 by vol.
5	61	52	91.2	"
6	62	52	115.5	"
7	62	52	153.8	"
8	62	52	112.7	"
10	35	45	99.0	"
9	62	52	54.3	"
2	28	40	49.7	Mortar 1 to 2 by wgt.
1	28	40	70.7	"
Pier	28	40	49.3	"

The table shows, roughly, that the beams built as regular masonry have a modulus of rupture of about twice the tensile strength of the mortar used. With the best construction it may be even three times the tensile strength of the mortar, as shown by beams Nos. 4 and 7. When built as piers, with no interlocking action, the modulus of rupture is about the same as the tensile strength of the mortar used. The experiments on deflections with beam No. 4, while not enough to draw any certain conclusions from, would seem to show that brick masonry is elastic, and that up to a certain point the deformation is proportional to the stress applied. The result of experiments in the past, while showing a certain transverse strength, have not been definite or uniform enough to furnish reliable conclusions. While the nature of this subject does not permit of its being carried in an experimental way as far as might be desired, without considerable expense, it is suggested that much can yet be done toward finding the strength actually obtained in brick buildings. The tearing down or failure of such buildings affords an excellent opportunity for this, and it is to be hoped that experiment and observation will be turned in this direction.

FOUNDATIONS.

No foundation is more ineligible for a heavy structure than one that is rocky, especially if the rocks are in small masses, or if a sufficient surface is offered of one mass, in strata which dip considerably: in the former case, from the rottenness of the soil in which rocks are generally bedded and which consists for the most part of their detritus; and in the latter, from the liability of stratified rock to crack and slip, against which no precaution is available. Dry gravelly soils, again, are not only loose and infirm, but are exceedingly liable to vacuities of various extent, which are hardly sufficiently provided against by piling; wet gravel is generally more compact and may be better trusted both with and without piles. A deep compacted sand will be found firm if a sufficient surface of it be embraced by the footings, which should be wider in that than most other cases. In large and deep beds of alluvial deposits the heaviest building may be laid with security, if precautions be attended to for the equal distribution of the pressure throughout. The city of New Orleans, in a delta at the mouth of the Mississippi, rests on a bed of mud, which is held together by a bonding of trunks and arms of trees, but on a broad level bed below. Here the only precaution taken in erecting a structure of the greatest magnitude is to make the trenches for the walls wide and level, and to floor the whole of their surface with thick planks properly bonded; on these the footings are laid, and if any settlement occurs it is of the whole edifice and no injury accrues to any part of it at any time. Clayey and chalkey soils are generally understood to form the best natural foundations; in these, under ordinary circumstances, no preparation is required, though for very heavy and unequally pressing works, such as bridges, which are placed on piers made as small as they possibly can be, piling has been considered a necessary precaution. Indeed, except perhaps on an extensive horizontal bed of firm compact rock, no foundation can be considered better than that afforded by piling in a deep clay

NOTES ON RECENT ADDITIONS TO OUR KNOWLEDGE OF PORTLAND CEMENT. *

By John Purser Griffith.

In his address to this institution five years ago the author made the following allusion to Portland cement: "The introduction of Portland cement has revolutionized the construction of marine works, and provides, when judiciously employed, the most useful cementing agent at our disposal. Cement concrete has naturally grown rapidly in favour on account of the facility with which it can be moulded into blocks or deposited *in situ* under water; and of late years it has been used in almost every work of magnitude in some form or another. Recently we have been startled by accounts of serious failures of works constructed with Portland cement concrete, and what may almost be termed a panic has taken the place of previous unqualified confidence. All manner of theories have been started to explain the deterioration of the cement. Additional tests have been suggested to detect these so-called dangerous properties, and numerous persons are to be found ready to predict the ultimate destruction of all works in which Portland cement has been used. It would be more profitable to investigate carefully each particular failure; to trace back the history of the work, the mode of construction, the proportion of cement used, and especially the manipulation of the concrete. My own experience leads me to think that we have nothing to fear if the material is fairly treated and a reasonable amount of common sense used." These remarks referred especially to Portland cement concrete which had occurred at the Aberdeen graving dock. As the details of these failures and others of more recent date have been made public by responsible engineers, and we are not dependen ton unauthenticated information, we are now at full liberty to discuss them, and any such discussion must be productive of good.

The reports of the disasters at Aberdeen produced a scare, resulting in what may be called the magnesium bogey. Chemical analysis of the disintegrated concrete showed the presence of magnesium hydrate in large quantities, and the conclusion jumped at by many engineers was that magnesia in the cement was the source of all evil. Tests were introduced to remedy this, and it was proposed, on high authority, that under no conditions was cement to contain more than 1 per cent. of magnesia. With one stroke of the pen English engineers proposed to remove from the category of cements useful for marine works the bulk of those used in the United States of America. With one stroke of the pen English engineers propose to nullify the experience of Chatoney, Vicat and Gilmour, who maintained that cements such as the Rosendale cements, which contain large quantities of magnesia, resist the dissolving action of the sea-water better than those composed only of the silicate and aluminate of lime.

It is satisfactory to know that further research and consideration has materially modified these views, and that it is now more generally accepted that the injury has been caused by the percolation of sea-water, than to the presence of magnesia in the cement. The effect of the flow of sea-water through Portland cement concrete appears to be identical with the effect of sea-water on lime mortar. This latter effect has been very fully explained by Dr. B. B. Stoney in a paper he presented to this institution many years ago "On the Action of Sea-Water on Lime Mortar," which may be found in vol. vii. of our *Transactions*.

The great lesson we have to learn from these failures is, that our concrete must be made impermeable. That appears to be the sum and substance of the various discussions on the subject, with which those of us who are members of the Institution of Civil Engineers must be familiar. At the beginning of the last session a most valuable paper on Portland cement was read in London by Mr. H. K. Bamber, a chemist evidently acquainted practically with the manufacture of Portland cement. The conclusions drawn may be briefly stated as follows: The cement should be very finely ground, not alone as making it an economical cement, but a safer and more reliable cement. The cement should be mixed with the full quantity of water it can take up. It was the author's privilege to have the opportunity of discussing these points with his friend the late Mr. Harry Napier Draper, who became so interested in the subject that he brought to bear on it the full powers of his cultured mind. Unwilling to approach the subject merely on information gained second-hand, he determined to manufacture Portland cement in his laboratory from its known chemical ingredients. This he succeeded in doing after several instructive failures. For our purpose it is sufficient to know that his experiments proved to him the need of subjecting the clinker to a sufficiently high heat and afterwards pulverizing it to the greatest possible extent. Mr. Draper's next step was to take a number of analyses of Portland cement which had been published. In these he found that the lime, silica, and alumina, which form the active constituents of the cement, averaged about 89 per cent. of the weight of the cement. Accepting Le Chatelier's theory, that the potentially active components of cement were tricalcic silicate and tricalcic aluminate, Mr. Draper proceeded to construct a rational formula on this theory, which would approximate to the known analysis of Portland cement. In Mr. Draper's formula lime represents 63 per cent. of the cement.

If this be true then cements containing this amount of lime could not be considered as over-limed—the lime being chemically combined. He next examined the reactions which followed mixing such a cement with water, and was able to confirm the views of Le Chatelier that by the addition of water a certain quantity of calcium hydrate was set free, though all the lime in the original cement was in a state of combination. Mr. Draper considered this freed calcium hydrate an important factor in the efficiency of cement, as it slowly combined with the siliceous sand, and also absorbed carbonic acid, forming the protective film noted by some writers. One of the most interesting points brought out by Mr. Draper's investigations was that if 89 per cent. of the cement consisted of tricalcic silicate and tricalcic aluminate, in the proportion indicated by his formula, and that the hydration reactions of Le Chatelier were correct, no less than 41 per cent. of water would be required to complete hydration. To those of us who are practically acquainted with the gauging of briquettes of neat cement, a proposition that we should use 41 per cent. by weight of water to mix the cement at first sight seems difficult to understand. We must, however, remember that Mr. Draper was referring to cement which throughout its bulk was potentially active.

Now, when we are speaking of the Portland cement of commerce, we must bear in mind that high authorities on Portland cement have agreed that the residue left after sifting cement through a sieve of 5,000 meshes per square centimetre, or 32,000 meshes per square inch, is practically inert, or at any rate sluggish in hydration. Now, in our English cements, with very few exceptions, from 30 to 50 per cent. by weight will be rejected by a sieve of this fineness. You will see, therefore, that this cement, instead of requiring 41 per cent. of water, will only demand about 20 per cent. for mixing into briquettes. Practical experience has shown us that this is sufficient, and the rules so generally laid down in this country that cement should be mixed with the minimum quantity of water has led to this proportion of water being generally adopted and adhered to, although the grinding of cement has improved. There is abundant evidence to show that briquettes immersed in water gradually increase in weight by the additional absorption of water beyond what was used in mixing the cement. It seems more than probable that this is caused by the slow hydration of the coarser particles. This gradual hydration of the coarser particles leads to their expansion, and this expansion is accompanied by the setting up of internal stresses in the briquettes or cakes. These internal stresses neutralize or negative the tensile strength, producing either a reduction in the strength of the briquettes or cracks visible to the eye.

In making briquettes with a deficiency of water you will frequently find that a very much higher stress is obtained at the early tests than if the proper quantity of water were used; this may be followed in later tests by a falling off in the strength of briquettes, while the briquettes mixed with an excess of water shows a large increase in strength. Much greater pressure can be exerted in putting cement into the moulds if it is in a granular condition than if it is plastic, and the high seven days' results may be due to the particles of cement being brought into closer contact when little water is used than when a larger quantity is employed. At the same time the stress set up by the hydration of the coarser particles will, of course, produce more injurious results in the dense under-watered briquettes than in those which were guaged with a large quantity of water. These points may possibly be made clearer by the following experiments with neat Portland cement, mixed with 20, 25, 30, 35 and 40 per cent. of water by weight:

Percentage of water by weight.....	20	25	30	35	40
Breaking stress per square inch, after 28 days, in lbs	840	685	540	385	375
Breaking stress per square inch, after six months, in lbs.....	804	830	680	530	515
Increase in strength per cent.....	—	24	26	38	37
Decrease in strength per cent.....	4	×	×	×	×

Such results have led some of us to think that a cement giving moderate breaking stresses at seven days and gradual increments at later periods, is a safer cement than one giving high results at seven days and little or no increase afterwards. This is a subject requiring further careful study, as there is much to be said for the contention of many German authorities, that a cement which attains at seven days 90 per cent. of its strength, at 28 days is superior to another attaining at seven days only 50 per cent. of its strength at 28 days. Free lime had been charged with most failures, due to the cracking of cement; but it seems difficult to understand how free lime could escape immediate hydration when guaged with what appeared to the eye a sufficiency of water. It has been very reasonably asked, if the slow hydration of the coarse particles is the cause of failure, how comes it that for so many years we have, with great success, used cements which were much coarser than those now in the market, and that these disasters have apparently increased as the grinding of the cement has improved? We must face this criticism, and endeavor to explain what we must admit to be a fact. The author's belief is that the old cement-makers burnt their cement more highly than is now done, that the clinker approached more closely to a state of fusion, and that the coarse particles were so vitrified that

* Paper read before the Institute of Civil Engineers of Ireland.

absorption of water, unless they were reduced by grinding, was almost impossible.

There is also another possibility—namely, that these comparatively large particles became surrounded by a watertight skin or coating of cement, which stopped their further hydration. The author is inclined to believe that the cements of the present day are not as highly burned as formerly, and that the slow hydration of the coarser particles is thereby facilitated. There are many leading authorities in Germany who stoutly maintain that the "idea that lightly-burned cement should be rejected is an erroneous opinion, if the present state of cement making and testing be considered, and that no cement is more reliable than one which gives good results, even when lightly burned." The meaning of this is that they recommend foregoing some of the advantages of high burning if it will ensure them a really finely-ground cement. Before we adopt any such proposition we must be prepared to insist on our cement being ground to the present German standard.

The time appears to have come when we may reasonably ask for finer cement than is now generally sold in the English market. We can get cement make in England at present which will entirely pass through the sieve of 2,500 meshes per square inch, leaving a residue of about 8 per cent. on the 5,800 sieve, and about 30 per cent. on the 32,000 sieve. But the author knows of no cement in this country which approaches in fineness some of the cements of Germany; for cement can be obtained in that country so fine that only a residue of from 3 to 10 per cent. remains on the sieve of 32,000 meshes per square inch, and, in some instances, so fine that it all passed through this sieve. To get such cement we must abandon high weight tests, as such a finely-ground cement will not weigh more than 70 lbs. per cubic foot in its dry uncompressed state. In this connection it may be worthy of remark that in the standard tests for Germany no tests are laid down for weight or specific gravity and it is a matter of considerable doubt whether we should retain such tests in this country, or even adopt a chemical test, as has been so strongly recommended by some chemists and engineers.

"Free lime" has long been the dread of engineers using Portland cement, and as a safeguard, many authorities have considered it desirable that cement should be stored for a considerable time and spread out in thin layers to "cool," or "air slake" It has been maintained that by so doing the cement is made safe for use, and that there will be no danger of its expansion and cracking. There are high authorities and scientific experts who now are equally positive that such treatment is not only not required with a high-class cement, but is actually injurious to it.

In the light of what has been discussed in this paper it is worth while examining these conflicting views. What are the effects of cooling cement with which we are familiar? First, the cement takes longer to set; second, the cement loses its strength; third, the cement increases in volume and consequently loses in weight. This "air-slaking" means the absorption of moisture and carbonic acid by the finest ground portions of the cement, rendering them inert and thus weakening the cement. If this air-slaking is continued sufficiently long the cement will become worthless, the coarser particles gradually absorbing moisture and carbonic acid. An examination of various analysis shows the presence of both moisture and carbonic acid in varying proportions. It seems more probable that air-slaking is a safeguard against under-burned and badly-ground cement than against the presence of so-called free lime. In such a cement the finely-ground portion of the cement would set rapidly, while the coarser particles hydrating at a later stage would swell and crack the cement. Air-slaking would, however, prevent this by rendering the finest portions of the cement inert through the absorption of moisture and carbonic acid, thus leaving only the coarser portions to act as cement. The natural result is, of course that after such cooling the strength of the cement is reduced. The true remedy seems to be the manufacture of a cement so finely ground as to be uniformly active, and if this cement is highly burned the results will probably be all the better.

In conclusion, the lessons we may learn from recent additions to our knowledge of Portland cement are: First, the paramount importance of fine grinding; second, the absolute need of using sufficient water to ensure the complete hydration of the cement; and, third, the necessity of making concrete exposed to the action of sea-water impermeable.

Mr. M. Ryan, brickmaker, of Smiths Falls, Ont., has made arrangements to operate all the machinery in his brickyard by electricity.

The Toronto Lock Co., who make an announcement in the advertisement pages of this paper, have lately commenced the manufacture in Toronto of the finer grades of builders' hardware.

With regard to ink erasers, Mr. James F. Hobart, of Brooklyn, N. Y., writes: In recent issues of Carpentry and Building, "J. W. G." and "S. P. G." recommend as good ink erasers broken glass and half worn sandpaper. They will do the work, but better results may be obtained by using a bit of rubber that has been prepared for erasing ink by having incorporated with it during the process of manufacture fine emery or other abrasive material. Separate pieces of ink eraser rubber can be had, or there may be purchased at any stationer's neat bits of polished wood with a piece of ink eraser projecting from one end and an ordinary pencil eraser from the other. After using the ink eraser it is well to go over the work with the ordinary rubber, in order to remove the grit that may remain.

USE OF LIME IN MORTAR.

There is a common superstition, which probably retains its hold upon builders solely through the profit that they find in maintaining it, but which, says the American Architect, sometimes really imposes upon laymen, to the effect that cement mortar is improved, in cold weather, by the addition of lime to it. As the mason ingenuously explains to his employer, the heat developed by the lime, in slaking, keeps the cement warm, and thus prevents it from freezing; and, on this theory, the advent of a frosty day is utilized by multitudes of sharp builders to load the mortar, which they have agreed to make of sand and cement only, with a quantity of lime, which saves cement, and makes the mortar easy to work, but destroys its water-proof qualities and injures its strength and hardness more or less, according to the quantity used. It is hardly necessary to say that the influence of the lime in "warming" the mortar is purely mythical. Lime mortar, without cement, is not much injured by freezing, while cement mortar is totally ruined, so that a mortar containing a large portion of lime would be harder, after freezing and thawing, than one containing cement only; but it would gain the qualities of lime mortar only as it lost those of cement mortar.

The fact is, that the only time when it is desirable to add lime to mortar, which the contract requires to be made with cement, is in the summer. In very hot weather, cement, particularly of the quick-setting sorts, will sometimes harden in the mortar-tubs before it can be used. The average workman chops up the lumps, and re-tempers them, with more water, but this proceeding destroys half the value of the cement, and it is preferable, under such circumstances, to add a small quantity of lime to the cement, at the first mixing. A very small dose of lime will retard the cement long enough to make it manageable, without materially injuring its properties, and circumstances sometimes render it absolutely necessary to resort to such an addition, in order to be able to work the cement at all. In winter on the contrary, the object to be aimed at is to accelerate the setting of the cement as much as possible, so as to place it beyond the reach of injury from frost, which, if kept out for twenty-four hours, has little effect on good cement. In order to secure this rapid setting, however, all traces of lime, which is a powerful retardant, must be kept out of the mortar, and the bricks or stones which are to be set with the mortar must be thoroughly warmed before they are laid. To warm the mortar is perfectly useless. A bed of mortar, spread on one cold stone, and with another cold stone lowered into it, will freeze completely through in a few seconds, even though it may have been boiling hot when it was spread; and we have seen in a warm day, with the temperature well above the freezing-point, stonework in cement mortar freeze almost as fast as it was laid, simply because the stones had been cooled down during the cold day and night previous, and had not time to get warm. It is obvious that, roughly speaking, it would require four tons of mortar at a temperature of forty degrees Fahrenheit, to raise a single stone, weighing one ton, from zero to thirty-two degrees, so that the whole mass would be just on the verge of freezing; yet the masons would have us believe that by adding a little lime to the mortar, they enable a hod-full of it, not only to raise above the freezing point the temperature of a large mass of masonry from a point in the neighborhood of zero, but to hold it there, notwithstanding the temperature of the surrounding air, until the cement has had time to set. By warming the stones, or bricks, the conditions are reversed. A heated stone will keep the mortar in which it is laid above the freezing point as long as it remains itself above that point, and as either stone or bricks lose heat very slowly, it is easy to build in the coldest weather, a wall which will retain, in the interior, a temperature above the freezing point long enough to make the cement in which it is laid secure against frost, except in the superficial portions; and with suitable coverings, these may also be protected. Mr. O. W. Norcross, one of the most ingenious and careful of builders, warms foundation-stones with a jet of steam, before laying them in cement in cold weather, but this is an expensive process, if thoroughly carried out, as the heat penetrates very slowly into the mass of the stone; and a better way is to pile the stone or brick over a furnace of some sort, in which a moderate fire can be kept night and day. We have once or twice made use of the low flat furnaces used by the workmen for heating pebbles who lay coal-tar concrete. Three or four thousand bricks can, with care, be piled over one of these furnaces, the chimney coming up through them, and by renewing them as fast as the hod-carriers take them from the pile, the masons can be constantly supplied with hot bricks, which will make excellent work with cement mortar, in the coldest weather; and as the furnace is tight, there is no danger of spoiling the appearance of the bricks by smoke.

A majority of the contractors of Montreal have acceded to the demand of the carpenters' union for a nine-hour day at 20 cents per hour. The new scale of wages will come into operation on the 1st of May.

The Mayor of Toronto has expressed himself as being in favor of the amalgamation of the Central School of Art with the Toronto Technical School. The art school is seeking to have the yearly grant from the city increased from $500 to $2,000.

PERSONAL.

Mr. Thos. F. Walker, of 237 Sumach street, Toronto, a well known contractor, died in Montreal on the 15th of March.

Mr. Thomas, a prominent and highly respected contractor, of Hamilton, Ont., died in Chicago last month. Deceased carried out the contract for the stone work on the City Hall and Bank of Hamilton, at Hamilton.

SHAVINGS.

Reports from London, Ont. indicate that building operations will be brisk in that city during the present season.

During 1893, the Toronto plumbing inspectors issued 946 permits, visited 1,331 buildings, made 9,235 inspections, including more than 1,400 smoke tests.

Mr. Lennox, architect of the new city buildings, Toronto, recently presented a statement to the council showing that since the city took charge of the work $198,600 had been spent. On an average 250 men had been employed daily, 250 cars of Credit Valley stone, 43 Cleveland, and 136 of New Brunswick, 2,352,580 bricks and 6391 barrels of lime has been used. Two and one half stories have been erected.

IN connection with the illustration of the Art Institute at Sackville, N. B., which appeared in our April number, the cost of the building was given as $54,000 instead of $24,000.

THE Executive Committee of the American Institute of Architects has unanimously approved of the course of their President, Mr. D. H. Burnham, in conducting his recent correspondence with the U. S. Treasury department, to which we refered in our last issue.

WE congratulate the Toronto Public School Board and the citizens generally on the action of the City Council in passing an appropriation of fifty thousand dollars for new school buildings to be erected this year. The Council could very properly have granted the total amount—seventy-six thousand dollars—asked for by the Board for buiding purposes, but considering the financial policy of this year, they did well by the Public School Board.

A DEPUTATION representing the labor societies waited on the Minister of Public Works at Ottawa recently and requested among numerous other things that the contract system in the construction of public works should be abolished. The report of the Commission in the Curran Bridge investigation and the experience of Toronto and other cities which have attempted to substitute day labor for contract work, should be a sufficient answer to the deputation in question.

THE Dominion Government in their latest revision of the tariff have reduced the duty on wire nails from 1½ to 1 cent per pound. Rolled iron or steel angles, channels, structural shapes and special sections, weighing less than 35 pounds per lineal yard, not otherwise specified, are to be charged 35 per cent. ad valorem, but not less than $10 per ton. On iron bridges and structural iron work the duty is made 30 per cent. ad valorem, but not less than one cent per pound.

IN our next issue we shall lay before our readers one of a series of articles prepared for the purpose of presenting some special subjects in a manner to make them of interest from the contractor's point of view. We expected to be able to publish the first of these in this number but found our space would not permit. These articles will be illustrated, and will deal with such subjects as the handling of large contracts, shoring for reconstruction of heavy buildings, modern appliances pertaining to contractors' plant, etc.

IT is to be regretted that no arrangement has yet been arrived at between the Ontario Government and the City of Toronto for the improvement of the avenue from Queen Street to the new Parliament buildings. From the city's standpoint there is no place where an equal expenditure would add more to its attractiveness. For the interests of the province it may be said that the opportunity for beautiful parliament buildings has been lost, but the situation of the buildings is one of great natural advantage, and careful treatment of the surroundings and approaches would add to their attractiveness. This work should not be delayed. The authorities should also consider in this connection the advisability of continuing the avenue directly south from Queen street through to Front street opposite the new Union Station. There are none but very cheap buildings in the way of such an extension and the new street frontages would be worth the whole cost. This would make the entrance to Toronto by way of the Union Station one such as few cities could boast.

THE commissioners appointed to investigate the management of the Lachine Canal and Curran Bridge affairs have reported that the whole business has been conducted with looseness, extravagance and questionable methods generally. This work has been carried on by day labor instead of being contracted for, and the Government is thereby loser of about two hundred thousand dollars. The responsibility is charged by each upon the other as between the Department of Railways and Canals and the local officers. The lesson to be learned from this affair is that no government, corporation or individual can have work of any kind done so economically by day labor as by contract; and when works of considerable magnitude are undertaken without the safeguard of a contract, the door is thrown open an I invitation given for loss and scandal to enter.

A PERUSAL of the new building by-law of the City of Hamilton, an abstract of which appears in our Hamilton correspondence, shows the newly appointed Building Inspector's duties to be multiform in character. In addition to seeing that in future construction work shall be done in the manner prescribed by the by-law, he is also assigned the duties which ordinarily belong to Plumbing and Health Inspectors. We take it therefore that the proposal for the appointment of a plumbing or sanitary inspector which has several times occupied the attention of the Council, will now be abandoned, and the salary of such an official saved. The clauses of the by-law forbidding the construction of eave troughs and down pipes in such a manner as to admit of water dripping upon the heads of persons passing along the streets and flowing across the pavement beneath their feet, is commendable, and might well be made to apply to building construction on the business streets of Montreal and other cities. The clause compelling the placing of snow guards on roofs is one the necessity for which was made mention of in these columns recently. The by-law seems in most particulars to be well adapted to the requirements. It will be the duty of the Building Inspector to see that it is not allowed to become a dead letter.

THE building season is now sufficiently advanced to make it clear that the volume of work for the year will be only moderate, and that it will be fairly distributed over the country. There is a good demand for work in the line of alterations and repairs outside of the mason's and bricklayer's trades, but the trades mentioned derive the least benefit from this class of work. There seems to be a peculiar combination of circumstances operating to retard increasing business activity pending further developments in some of the factors in the situation. Among the influences compelling great caution may be cited, the unsettled tariff discussions at Ottawa and Washington, the question of England's embargo on Canadian cattle being removed, the near approach of elections, etc. The wonder is that business of all kinds in Canada has not been more seriously disturbed during the past few months. Such improvement in the conditions as may reasonably be expected cannot much affect the volume of business in the building trades for this year. Therefore, while it is necessary for us all to give the best possible attention to the work in hand and to the immediate future, we would suggest that the greater interests of all connected with the building trades lie beyond the months remaining of 1894, and that the true basis for future development is to be found in the question of immigration. Canada's greatest need is a much larger agricultural population, always having regard to kind as well as numbers. Only as agriculture is developed can building industries be maintained. Although without any immigration there will be a certain amount of growth and demand for building work we should be very stupid to lose sight of the opportunities plainly before us. Canada has all the manufacturing, mercantile, and transportation facilities for conducting the business of a much larger population than she at present possesses. In fact, these very facilities have been developed largely in anticipation of increased immigration. With such an immigration the building industries would be taxed to keep up with the requirements. No other class of business would receive equal benefit from this source. The government is making strong efforts to induce immigration, but the results so far this season are disappointing. We must not be discouraged if the returns seem slow, but rather let us be determined to devise the necessary means to accomplish the desired object. If those engaged in the various branches of the building industries were thoroughly alive to their own welfare and prepared to unite on this question they would find themselves possessed of brains and influence sufficient to materially assist in the solution of the problem.

IT is to be feared that the building contractors of Canada are dropping behind the business men in nearly every other line of equal importance, in their lack of organization for the advancement and protection of their common interests. We have plenty of contractors who as individuals are good and live business men, but as a body they are not known except in a comparatively small way. The existing organizations among builders are few, but are deserving of commendation for their good work and are examples worthy to be followed. The Toronto Builders' Exchange is no doubt the leader, and is destined to steadily increase its usefulness so long as its affairs continue to be guided by capable hands. If contractors have not yet thought it worth while to organize more extensively from the standpoint of general progressiveness, it is about time that they should combine for purposes of common defence. We notice that the trades unions are working aggressively in season and out of season to secure recognition, and there is no doubt that they gain ground in this way. Among their latest successes is the securing of municipal legislation making it compulsory that in civic work contractors shall pay union wages. They are now seeking to have this stipulation inserted in all contracts for public works from those of School Boards up to those of the Dominion Government. We do not say nor do we think that trades union agitation is all conducted with wisdom, but the trades unions are alive, and they are gainers by their activity. There is legitimate work for them and for others to do through organization. The architects, too, are making progress by means of their associations, and they have interests that make it necessary for them to carry on and enlarge their association work. The work and business of contractors is hedged about with many protections for other people. In the first place there are the contract drawings and specifications; next the superintendence of the architect or clerk of works; then trades union rules, municipal building regulations and the Employers' Liability Act, with penalties of all sorts to protect everybody from the contractors. These things are all quite proper up to a certain limit, but there exists no doubt a contractor's side to the business. Doubtless there are instances in which a contractor may suffer an injustice simply because single handed he is unable to put up the costs in expensive law suits. Suppose that such a contractor had the assistance of an organization in testing his case in a manner similar to the method followed by the architects of France. In that way wrongs would be righted, and every such test case would help to remove friction and to stop bad practice all around. This is only one way in which contractors can work together to advantage. In the arbitration method for the settlement of labor troubles or their adjustment by Government Commission, contractors cannot afford to take their chances single handed any more than in suits at law. There is work to be done on behalf of the contractors that none but themselves can do, and we would urge them to greater activity in this direction. Wherever union labor is found there should united contractors be found also. By this means alone can all interests be properly counterbalanced.

ILLUSTRATIONS.

BANCO DI SAN SPIRITO, ROME.—DRAWN FROM PHOTO, BY J. C. B. HORWOOD.

C. A. & B. COMPETITION FOR DRUG STORE.—DESIGN SUBMITTED BY "ITALIA" (MR. MELVILLE MILLAR), AWARDED FIRST POSITION.

DESIGN FOR COTTAGE TO COST $1,000.—SUBMITTED BY "DEMOS."

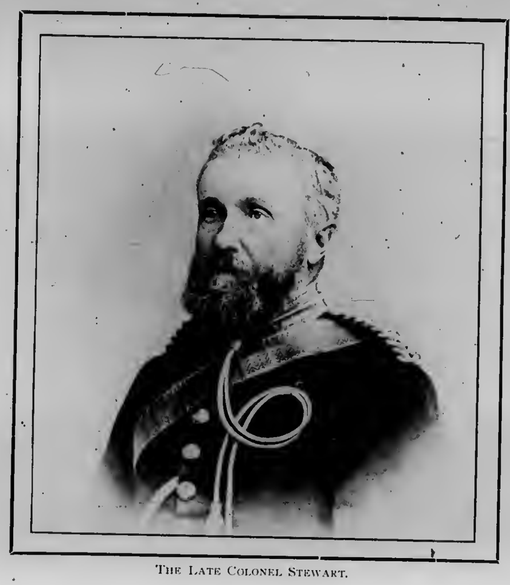
This cottage, to cost about $1,000, contains seven rooms and bath room, and is designed to face the east. To be of frame construction on stone foundation. Walls to be clapboarded, as shown, or hung with shingles. Roof to be shingled.

THE LATE COLONEL STEWART.

IT has become our painful duty to chronicle the death of Col. John Stewart, of Ottawa, the contractor for the new Toronto Drill Hall. His death, which occurred at his son's residence in Toronto, on the night of the 4th of May, was totally unexpected, being due to heart disease with which deceased had for some time been afflicted.

The subject of this notice was born at Dungiven, Londonderry County, Ireland, on the 11th January, 1835. After leaving school he learned the joiner's trade. In 1857 he emigrated to Canada, and settled in Ottawa, which, during the remainder of his life, was his home. After working at his trade for several years, he received in 1862 his first contract, which was to build a residence for the Governor-General's secretary. In 1868 he formed a partnership with Mr. Stockand, which was dissolved in 1874.

Deceased rapidly achieved a prominent position as a contractor of more than ordinary skill and integrity, and was entrusted with the carrying out of many important undertakings. Amongst these may be mentioned the extension of the Western block of the Dominion Parliament Buildings, the construction of the Mackenzie tower, the Supreme Court buildings, alterations on the Grenville canal, experimental farm buildings at Brandon, Mounted Police riding school at Regina, the new Drill Hall at Toronto. Upon the latter building, now nearing completion, he was engaged, when death so suddenly closed his career.



THE LATE COLONEL STEWART.

The late Col. Stewart filled with credit to himself and advantage to the community, a number of public positions. In 1878-9 he occupied a seat as alderman in the Ottawa City Council, and was a member of the Board of Works and other important committees. He was an ardent military man, having risen from the ranks to the position of Colonel of the Ottawa Field Battery.

Deceased was twice married, his second wife and eight children being his survivors.

The obsequies, which took place at Ottawa, were of a military character, and were also marked by many tokens, floral and otherwise, of the high esteem in which the deceased was held throughout the country. His portrait in the uniform of a Colonel of the Ottawa Field Battery, is herewith presented to our readers.

RAISING.

There is no part of the construction of a frame building which requires more care or accuracy, says Owen B. Maginnis, than the raising of the frame. I therefore trust that my remarks on this subject will be carefully read as they will be found very applicable in practice. Placing cellar girders: These will require to be lifted into the place on top of the piers built for them in the cellar, or set perfectly level and straight from end to end. Some prefer to give their girders a slight crown of say ½ inch in the entire length, and it is a wise plan, because the piers generally settle more than the outside walls. When there are posts instead of brick piers used to support the girder, the best method is to temporarily sustain the girder by uprights made of 2 x 4 joists resting on blocks on the ground below. When the superstructure is raised these can be knocked out and the permanent posts placed, resting their bottom ends on a broad flat stone, to form a base or foundation footing. If the supporting posts or piers be not placed or built until after the building is erected, then carpenters should exercise good judgment when jacking the girders up, to place them under it and not raise them so much as to strain the building, and it is always desirable to obtain the crown mentioned before. The practice of temporarily shoring the girders, and not placing the permanent supports until after the superstructure is finished, is favored by good builders, and it would be well for carpenters to know just how it should be done. Setting the sill: After the guide is in position the sills are placed on top of the cellar walls, rounding side up and hollow side out, and are very carefully fitted together at the joints and levelled throughout. The last operation can either be done by a sight level or by following the simple method I am now about to describe: Place ⅞-inch blocks at intervening distances on the length of each side, also one at either end, and set a long parallel straight edge on them, also set a true level on the upper jointed edge of the straight edge. The sill must be wedged up, or lowered down until the air bubble in the level tube is exactly in the centre, and each piece must also be wedged up or lowered till the blocks all touch the bottom edge of the straight edge. In all cases the whole length of the sill should bear solidly on the stone work, and it should either be bedded in mortar or made solid with chip pieces of slate, stone wedges or furrings, and these should not be inserted less than two feet apart. Sills are generally kept back ⅞ or one inch from the face of the stone-work, to make the sheathing come flush with it, and allow the water table to project the thickness of itself (usually 1¼ or 1⅜ inch) to keep the water off the stone. Sills must be taken out of wind, that is to say, they must be level all around, so that when the carpenter sights them with his eye (the other being closed) the surfaces will show as one line. All sill joists will require to be toenailed or spiked to draw them closer together, and the running joists should be nailed dovetail fashion. When sills are made up of two thicknesses of plank, as they sometimes are, they will need to be solidly spiked together, to form one with dovetailed nails. As some of my readers may not clearly understand what is meant by "dove-tailing" nails I will here state that a carpenter dovetails nails when he drives two with the points inclining to or from each other, so that they form, as it were, a "dovetail."

WATERPROOF CELLARS.

A cellar can be so constructed as to be waterproof if the bottom or the floor is first covered with cement, the walls built thereon laid in cement and the exterior of the walls covered with cement.

This makes practically a watertight basin. The cement used must be the best Portland cement, one part; clean sharp sand, one part. After a cellar is built it is not so easy to make it waterproof. Still it can be done. Cover the exterior of the wall with the above cement, ditto the bottom, and work the cement in under the bottom of the wall.

If these directions are followed, you will succeed. But if cheap materials are used, and the work badly done, you will be sure to fail.

BRITISH COLUMBIA.

(Correspondence of the CANADIAN ARCHITECT AND BUILDER.)

THERE is very little in the way of building news to report at present as architects and builders in this province in common with those in other countries are feeling the effects of the world-wide commercial depression.

The only piece of news I can think of at present is in connection with the new post office and customs house in Victoria. Things being so quiet, the Council of the British Columbia Institute of Architects thought it would be beneficial to the provincial architects if the new public buildings were open to competition among them, and therefore on the 19th February of this year wrote to the Minister of Public Works—Hon. Y. A. Ouimet—pointing out the advantages, etc., to be gained by such a course; reminding him of the fact that for the Victoria Legislative Buildings, for which 65 plans were submitted, we had two in the first five in the Province, and it is now being carried out by a local man. This letter, by an oversight, I suppose, was never acknowledged, although it was backed by our two senators and four of the local members. The only intimation that the request has been refused is contained in the enclosed cutting which appeared in the Ottawa Correspondence of the Victoria Colonist on 1st April. The paragraph speaks for itself:—

"Col. Prior and Mr. Earle have been busily engaged in the departments during this week. Both are anxious to push the officials of the Public Works department, so that a start may be made on the new public buildings at Victoria as soon as the next fiscal year commences. The architects of the department are busily at work on the plans, the application of the B.C. architects to be allowed to compete amongst themselves for the preparation of the plans and specifications having been summarily refused, as was to be expected. While, doubtless, professional men in your Province would have been glad to have had the opportunity to have made the drawings of the new buildings, when it is considered what a precedent would have been created if the request had been granted, little wonder that the Government refused it. A staff of architects, under the charge of Mr. Fuller, is kept at the department for the purpose of carrying out this kind of work. Mr. Fuller himself is one of the most competent men on the continent of America. Against a large field of competitors he won the first premium with his plans of the present Parliament Buildings in this city, and after that beautiful building was completed Mr. Fuller was successful in gaining the first prize for his plans of the present capitol at Albany. The fact that he was successful in securing these important prizes in his profession is conclusive proof as to his ability. Mr. Fuller has made a rough sketch of the proposed building at Victoria, which it is expected will cost from $250,000 to $300,000, but when I spoke to him a little while ago he was then inspecting the grades of the street in the vicinity of the site before getting down to real work. The two members from your city are satisfied that the Government will put up a building which will be as much a credit to the Dominion as it will be to the city."

HAMILTON, ONT.

(Correspondence of the CANADIAN ARCHITECT AND BUILDER.)

The City Council have appointed Mr. John Anderson City Building Inspector, at a salary of $650 per year.

I forward to you for publication as a matter of interest to your readers in this and other cities the clauses affecting architects and contractors contained in the new Building By-Law which has recently been adopted by the City Council of Hamilton.

2. The Council shall from time to time appoint a competent, practical and discreet man to be inspector of buildings and of fire limits and private drains.

3. The duties of the Building Inspector shall be as follows:

(a) He shall receive and take good due care of all plans and descriptions of buildings deposited with him under the provisions of this By-Law and record the same in a book to be kept in his office for that purpose, and shall keep such book properly indexed and open for inspection and reference, and issue permits in accordance with the terms of this By-Law, and he shall also record in a book to be kept by him all reports and complaints made to him as Building Inspector.

(b) He shall inspect all buildings while being erected, altered or enlarged within the City, and all scaffolding put up or used in connection therewith, and also the erections placed by the builder or contractor upon any street, lane or alley adjacent to any such building or any obstruction or want of repair in any such street, lane or alley caused by the deposit of building material or by the carrying on of the works.

(d) He shall inspect the drains of all buildings in the course of erection, and also all drains made or re-laid from any buildings already erected and see that such draining is done in a thorough manner, and shall keep a record, of every inspection, and of his decision and action thereon in a book to be provided by the Corporation for that purpose, and shall make in such book a small diagram showing the location of each drain therein referred to.

(e) He shall inspect the drains connected with or leading from or situate in any building or premises in the City of Hamilton when requested by the Medical Health Officer, or by the Sewer Committee, or the chairman thereof, to do so, and if he finds the same to be out of repair or not properly constructed, or otherwise defective, or the drains not properly trapped or ventilated, he shall notify the owner or owners thereof in writing, calling their attention thereto and calling on them to re-construct, alter or repair the same.

4. It shall also be the duty of the Building Inspector to enforce the provisions of this by-law, and that he may able to do so in all respects, the Street Commissioner shall notify him of the intended construction or reconstruction of any pavement where conductors or gutter pipes are to be connected with the sewers under section 35 of this by-law, and also of any violation which may come under his notice of the provisions of this by-law affecting the streets, sidewalks, pavements or sewers of the city.

5. All that part of the City of Hamilton embraced in the following limits or boundaries shall hereafter constitute and be known as the fire limits of the City of Hamilton: Commencing on the westerly limit of Wentworth street at its intersection with the lands of the Grand Trunk Railway Company, thence southerly along Wentworth street to the lands of the said Company, formerly belonging to the Hamilton & Lake Erie Railway Company, thence in a northwesterly direction along the northerly limit of said lands to Young street, thence westerly along Young to Ferguson avenue, thence southerly along Ferguson avenue to the John street mountain road, thence in a southwesterly direction along said road to the point where that road is intersected by the short road leading up the mountain in a southwesterly direction from the head of John stree, thence in a straight line in a northwesterly direction to Aberdeen avenue at its intersection with the James street mountain road, thence westerly along Aberdeen avenue to Locke street, thence northerly along Locke street to King street, thence westerly along to Dundurn street, thence northerly along Dundurn street and in continuation of the line of that street to the lands of the Grand Trunk Railway Company, thence in a straight line in a southeasterly direction to Barton street at its intersection with the east side of Oxford street, thence easterly along Barton street to Queen street, thence southerly along Queen street to Clarence street, thence easterly along Clarence street to Hess street, thence easterly on Cannon street to Railroad street, thence northerly on Railroad street to Mulberry street, thence easterly on Mulberry street to Bay street; thence northerly on Bay street to the southern limit of the lands of the Grand Trunk Railway Company, thence easterly along the southerly limit of the lands of the said Company to the place of beginning.

6. No person shall commence the erection of any building or part of a building, of the cost of more than $100, within the City until he shall have deposited with the Building Inspector a ground or block plan showing the level of the cellar and basement thereof with reference to the grade line of the adjoining street or streets as laid down or recorded in the office of the City Engineer, and also a description showing the materials with which the walls of the building are to be constructed, and has obtained a permit from the Building Inspector to proceed therewith. Every contractor or builder shall produce to the Building Inspector for inspection whenever required by him, the plans of any building which such contractor or builder may be erecting within the City Limits.

7. Every building, or part of a building made, constructed or placed within the said fire limits, shall be built with outer walls of iron, stone or brick, and when such building or part of a building is built with outer walls of iron, such walls shall not be less than one eighth of an inch of iron in thickness; when the outer walls are built of stone or brick, and such building or part of a building is more than one-and-a-half and less than three storeys in height, the outer walls shall be at least eight and one half inches in thickness, and when three storeys in height, the outer walls of the first and second storeys shall not be less than twelve inches in thickness and of the third story not less than eight and one half inches in thickness, and when more than three storeys in height the outer walls of the first story shall not be less than sixteen inches in thickness and of the second storeys not less than twelve inches and of the upper storey not less than eight and one-half inches in thickness,

(a) Every mansard roof shall for the purposes of this by-law be considered as a story, and such storey must be divided by brick or stone partition walls as hereinafter provided when such partition walls are extended to the story next below it.

(b) Every building within such fire limits which is to be divided into one or more stores, tenements or dwellings, and whether the same is being newly constructed or is being altered or rebuilt, shall be so divided by brick or stone partition walls running from the front to the rear of such building and extending from the foundation to the full height of each partition, such partition walls to be not less than eight and one-half inches in thickness, if not extending more than three storeys in height, but if extending beyond that height, such partition walls up to and inclusive of the third storey shall be not less than twelve inches in thickness and the partition walls above the third storey shall not be less than eight and one-half inches in thickness, and all such partition walls where they divide the top storey of a building shall be continued and built up to a height of twelve inches above the roof.

(c) Where any hall or large room is to be constructed on an upper storey, and is to extend over two or more of such stories, tenements or dwellings, the party walls shall be carried from the foundation to the top of the floor joist of such a hall or room, and the flooring of said hall or room where passing over the tops of such partition walls shall be solidly bedded upon a half inch coating of asbestos mortar.

(d) In all cases the ends of any and all joists resting in or upon any wall or partition shall be at least four inches apart in each direction and any space intervening between the ends of such joists shall be filled with brick and mortar.

(e) No wall or part of a wall of any tower within the City Limits shall be built upon any wooden beam or wooden girder or support.

(f) Every elevator shaft shall be constructed with brick walls not less than eight and one-half inches in thickness, with iron doors to each opening, commencing at the lowest point reached by such elevator and extending at least five feet above the roof of the building, and the roof of each elevator shaft shall be formed by a skylight.

8. Any one or two storey frame building already erected may be bricked up with four-inch brick walls within said fire limits, if placed on a stone foundation,

9. All roofed buildings within the fire limits shall be finished externally with tin, iron, zinc, copper, slate, tile or felt and gravel, or with shingles laid in hair mortar, not less than one quarter of an inch in thickness, or with shingles laid on fire-proof felt or with some other material of an incombustible nature, and no roof of any building already erected in the said fire limits shall be re-laid or re-covered except with materials hereinbefore enumerated.

10. Nothing herein contained shall be so construed as to prevent the erection within the said fire limits of any building constructed of material other than with walls of iron, stone or brick, not exceeding 216 square feet in area and 16 feet in height at the highest part of the roof thereof, or to require such building to be roofed in the manner hereinbefore directed, provided such building shall not front upon any street; nor shall more than one such frame building be erected on the same lot or premises. No building with outer walls other than of iron, stone or brick, shall be built within the area bounded by Ferguson avenue on the east, Hunter street on the south, Bay street on the west, and Cannon street on the north; or within the area bounded by Ferguson avenue on the west, Main street on the south, Wellington street on the east, and King William street on the north.

11. No building or part of a building within the fire limits, other than with main walls of brick, stone or iron shall be raised, enlarged or removed to any other place within the same, nor shall any such building be removed into the fire limits; nor shall any wooden building within said limits which may hereafter be damaged to the extent of fifty per cent. of the value thereof be repaired or rebuilt, nor shall such building, where the damages are less than fifty per cent. of its value, be so repaired as to be raised an additional storey, or so as to occupy a greater space than before the damage thereto, but nothing herein contained shall prevent any one from putting a stone or other substantial foundation under any existing wooden building, such foundation not to be more than four feet above the established grade of the adjoining street, nor shall it prevent any one from removing a wooden building towards the rear of the lot on which it stands, provided it is not placed within two feet of the land of any adjoining owner, or of any other wooden building on the same lot or premises.

12. Any owner or contractor who shall build or aid in the erection of any building or any part of a building within the fire limits, or shall remove or assist in removing any such building, or shall repair or assist in repairing any damaged building contrary to any provisions of this By-law, shall be subjected to the penalties hereinafter imposed.

13. Any building or erection which may be constructed or placed in contravention of this By-law may be pulled down or removed, at the expense of the owner thereof, by or under the direction of the Building Inspector, but it shall be the duty of the inspector, before pulling down or removing such building or erection, to obtain the consent of the Market Fire and Police Committee or of the Mayor to his so doing, and to give two days' notice to the owner or builder requiring him to pull down or remove such building or erection.

14. All public buildings, hotels, halls, theatres, factories and schools more than two storeys in height shall be provided with two or more fire escapes, securely fastened to the outer walls of such building, hotels, halls, theatres, factories or schools, and connected with one or more windows in each storey except the first.

16. Every chimney within the limits shall be carried to a height of not less than six inches above the ridge or deck of any roof carried by or connected with or abutting upon the walls to which said chimney is attached, and where a chimney is used to carry away smoke or noxious vapors from any manufactory where an engine and boiler of more than twenty-horse power are used, such chimney shall not be less than seventy-five feet in height above the level of the street adjoining such manufactory, and shall be built entirely of brick, laid with good mortar.

17. No timber shall be placed within one foot of the inside of any oven, copper still, boiler or furnace, nor within four and a half inches of the inside of any flue.

18. No person shall hereafter place any furnace or stove in any house or building in the city, without leaving twelve inches clear from any wood-work immediately above such furnace or stove, and nine inches from any wood-work opposite the sides of the same, and no person shall place, or maintain or use any furnace upon or over a wooden floor unless there is immediately underneath the furnace and extending a distance of four inches on each side beyond the outer walls of such furnace a bed of concrete not less than six inches laid in mortar, and there is also an air space of at least three inches between the furnace and such bed.

(a) All open fireplaces or grates shall have the hearth laid upon trimmer arches of brick or upon iron girders.

19. No pipe or funnel conveying steam or hot air shall be fixed next any public street or highway on the front of any building, nor shall any exhaust steam pipes be allowed to enter any sewer, nor shall any funnel, pipe or flue for conveying fire or smoke be fixed on the inside of any building nearer than twelve inches to the face of any timbers or roofs, ceilings or partitions; nor shall any such funnel, pipe or flue pass through any timber framing, or partition of wood, or wood or lime, or through any wooden floor, in any house, outhouse, fence or building whatever, within the said City, unless there shall be a space of at least six inches clear between the said funnel, pipe or flue and such framing, partition or floor, and unless the same shall pass through a chimney of stone, or brick or mortar, or shall be encircled by a rim of solid stone, or brick or metal, not less than three inches wide, and equal in thickness to the full finished thickness of the framing through which such pipe shall pass.

24. When any building, buildings or scaffolding in course of erection within the City limits shall be considered unsafe by the Building Inspector, he shall at once notify the owner, contractor or agent to make the same safe and secure, and every person notified, who fails within twenty-four hours to comply with such notice, shall be subjected to all the penalties of this By-law.

27. No person shall deposit or place in any public street, land or alley in the city any material to be used in the erection of any new building, or the repair or alteration of any old building, at a cost of over $100, until a plan and description in accordance with the requirements of section 6 of this By-law have been deposited with the Building Inspector, and such person has obtained from the inspector a permit in writing in the form appended to this by-law for the placing of such material in such street, lane or alley, and in all cases where such plan and description have been so deposited, and it is necessary to use any portion of such public street, lane or alley, for the placing of such material, the Building Inspector shall give a permit in the form appended to this By-law.

28. No person shall, either personally or through any one acting for him or with his authority, deposit or place any building material in or upon any public street, lane or alley within the limits of the city, except for the purpose of building or repairing, and in every case such building material shall be so placed as not obstruct the surface drainage of such public street, lane or alley, or the free use of any public hydrants, or to occupy more than is necessary of such public street, lane or alley, and in no case more than one-third the width thereof in that portion of the city bounded by Catharine, Hunter, Bay, and Cannon streets, and in that part of King street between Catharine and Wellington streets, no more than one-half thereof in any other part of the city, the space so occupied not to extend along such street, lane or alley, further than the frontage or depth of the lot so being built upon except that it may extend in front of the lot on either side, so long as the occupant of such adjoining lot may consent thereto; provided always that if the owner or tenant of the real estate on the opposite side of the street, lane or alley shall require at the same time to use any portion of the street, lane or alley for the deposit of building material, then, in such case each party shall be restricted to use one-fourth of such street, lane or alley instead of one-third as aforesaid in that portion of the city bounded by Catharine, Hunter, Bay and Cannon streets, and in that part of King street between Catharine and Wellington streets, and to the use of one-third of such street instead of one-half thereof in any other part of the city, but every lane or alley must be kept open for traffic to a width of not less than eight feet, and such material shall not in any case be allowed to remain in any public street, lane or alley, for any longer time than may be reasonably necessary for the completion of the work for which such building material is being used.

29. Every person who shall deposit or place any building material upon any public street for any of the purposes hereinafter mentioned in that part of the city bounded by Catherine, Hunter, Bay and Cannon streets, or in that part of King street between Catherine and Wellington streets, shall, while any part of the material remains upon such street, enclose and keep enclosed the ground thereby occupied with a close board fence of a uniform height of not less than six feet, the public sidewalk to be left clear in all cases where it is not necessary to occupy it, and to be roofed over, wherever necessary, at a height of not less than eight feet above the level of the sidewalk with two thicknesses of one inch boards, and where it is necessary to occupy the sidewalk with building material, a plank sidewalk three feet wide shall be made by the person depositing the building material, such sidewalk to be made immediately outside of the said fence, and the ground covered thereby shall be reckoned as part of the space which the person depositing the building material is allowed to occupy.

30. Every person who shall deposit or place any building material upon any public street for any of the purposes hereinbefore mentioned in any part of the city other than that portion thereof bounded by Catherine, Hunter, Bay and Cannon streets, or that part of King street between Catherine and Wellington streets, shall, while any part of the material remains upon such street, enclose and keep enclosed the ground occupied thereby with a board fence at each end of sufficient height and strength to fully protect the public from injury or danger therefrom, and if the public sidewalk shall be enclosed within such fences, he shall make a sidewalk three feet wide immediately outside of said enclosure, and the ground covered by such sidewalk shall be reckoned as part of the space which the person depositing the building material is allowed to occupy.

31. The fence, roof and sidewalk mentioned in the preceding paragraphs of this section shall be removed by the person by or for whom they were erected as soon as the building material enclosed thereby has been used or removed, and he shall also thereupon put the street and sidewalk where such material has been deposited in as good repair as it was before such material was placed thereon.

32. Whenever any person or persons, whether contractors or proprietors, shall be engaged in the erection or repairing of any building or other structure whatever within this city, and shall cause or permit any building material to be placed on any public street, lane or alley in the said city, and whenever any person or persons who shall be engaged in constructing any sewer or laying any gas, water or other pipes or conductors, in or through any of the streets, lanes, alleys, highways, sidewalks or other public places in said city where persons pass and repass, whether by appointment of the city or its agents, or its contractors, or otherwise, it shall be the duty of all such persons to protect the public from injury therefrom by placing a sufficient number of red lights upon such materials, rubbish, goods, wares and merchandise, heaps, pits, excavations or any other thing so caused or permitted by them to be or remain in or at any of the places above mentioned, and in such manner as to enable the same to be distinctly seen by all passers by and to continue such lights from dusk till daylight, during every night in which any such obstructions are allowed to remain in or at such place, and if such materials or obstructions are enclosed by a fence such lights shall be put on or above the fence, and no person shall, without the consent of the person or persons placing such lights, put out, remove or obstruct the same, or any of them, between dusk and daylight.

33. No person shall allow building material of any kind under his control to remain in any public street, lane or alley after dark without being closely piled, and being also sufficiently lighted in the manner hereinbefore required, or to remain in any public street, lane or alley, in any other manner or for any other purpose, or for any longer time than is permitted by this by-law, nor shall any person put any fence or obstruction or allow any fence or obstruction under his control to remain in any public street, lane or alley, in any other manner or for any other purpose, or for any longer time than is permitted by the provisions of this by-law.

35. No owner or occupant of any building shall place or construct, or authorize the placing or construction of any eavetrough, conductor, water-pipe or gutter pipe so as to permit or cause the water from the roof of such building to escape upon, flow over or run across or upon any public sidewalk, and the owners of buildings hereafter erected or built shall connect all conductors or gutter pipes upon that part of the building abutting upon any street with the sewer upon such street, if any there be, and whenever the pavement upon any street, not being a wooden sidewalk, is being constructed or reconstructed, the owners of all buildings abutting upon the street shall connect with the sewer, if any, upon such street every conductor, water pipe or gutter pipe, the water from which would otherwise flow over or upon such pavement.

36. No porch, or bay window, or steps, or other structure shall encroach upon or extend over the line of any street or alleyway.

38. Before any part of a private drain or sewer laid or constructed in or from any building or buildings in the City of Hamilton shall be covered up, or enclosed, or hidden from view, it shall be the duty of the drain layer, or other person or persons having charge of the laying or construction of such drain or sewer, to give notice in writing to the Building Inspector, or at his office, that such drain or sewer is ready for inspection by him, and he shall thereupon, without delay, inspect the same, and it shall be unlawful for any drain layer or other person or persons to cover up, or enclose, or hide from view any part of such drain or sewer until the Building Inspector has approved of the same, except in cases where from the presence of quicksand or from the nature of the soil it is impossible to keep the drain or sewer open for inspection.

(a) No brick or wooden drain shall be allowed within any building, but all drains within any building shall be of heavy cast iron pipe or of salt-glazed vitrified sewer pipe. Cast iron pipe when used within any building shall be oil finished inside and outside, with joints caulked with oakum and molten lead. All cast iron pipe when laid beneath the surface within any building, shall be not less than one-third of an inch thick. Vitrified sewer pipes when laid within any building shall be of the make known as *double strength*, and shall be of a thickness of not less than one-tenth the diameter of the pipe; the flange shall be not less than one and three-quarter inches deep; all flanges shall be carefully filled with the best Portland cement. The upper surface of any sewer pipe shall be not less than four inches below the foundation of any wall under which it passes.

39. If on examination of any private drain or sewer it is found that the same is out of repair, or is not properly trapped or ventilated, or is in a condition that is likely to be dangerous to health, the Building Inspector shall give notice in writing to that effect to the owner of the premises with which such drain or sewer is connected, and if for thirty days after receipt of such notice such owner or owners shall have refused or neglected to make all proper repairs or alterations he or they shall be liable to the penalty imposed by this by-law, and such penalty may be imposed for every day after the expiration of thirty days that such refusal or neglect shall continue.

41. Any person or persons guilty of a breach of any of the provisions of this by-law shall, for every such breach be subject to the penalties imposed by chapter seventy-one of the Consolidated By-laws of this City.

The management of the Toronto Technical School have decided that the drawings made by the students of that institution should be exhibited at the Toronto Industrial Exhibition.

The Grand Trunk Railway Company against whom the courts recently gave a verdict for $3,500 in a suit brought by Mrs. Dr. Oldright, for injuries sustained by falling into an excavation at the new Union Station, will now fight the matter out with the contractor, Mr. McDermid. Mr. Justice Street in the previous case expressed the opinion that the contractor was not liable for the accident.

The Engineering Society of the School of Practical Science, Toronto, have elected officers for the ensuing year as follows:—President, A. E. Blackwood; Vice-President, I. Armstrong; Recording Secretary, J. C. King; Librarian, F. H. Guernsey; Corresponding Secretary, F. J. Robinson; Treasurer, T. D. Wright; Fourth Year Representative, R. H. Angus; Third Year Representative, R. J. Campbell; Second Year Representative, E. P. Lea; Representatives on Varsity staff, Editor, J. E. Moore; Business Manager, E. W. Macpherson.

WINNIPEG.

(Correspondence of the CANADIAN ARCHITECT AND BUILDER.)

As the remarks made by your correspondent in his letter for March, re New Court House Addition, Winnipeg, together with Mr. Wheeler's letter, which appeared last month, have aroused public interest in the matter, no doubt the following paragraph, with which the Free Press, April 5th, 1893, closed a long article on the subject, will prove interesting reading to your western subscribers :

"Some interest is felt by the legal profession in the plans of the new court house, as well as the site. Of the plans submitted that of Geo. Browne is generally regarded as the most suitable, and it is said, should be the one selected. Influences are at work, however, in Government circles, so the Free Press is informed, that give the loudest Government shouter the inside track. But it is regrettable that in a large and permanent addition to the architecture of the city, business methods should not prevail, and the best man and best plan be selected."

The wet weather we have been enjoying, or otherwise, has delayed building operations, which is most unfortunate for the working men, who have been looking forward to the spring work to enable them to earn something for themselves and families, after their enforced idleness during the winter months.

After much discussion the Winnipeg School Board passed a resolution last night, authorizing the Building Committee to obtain plans for an eight room school building, to be erected on the site of the present Argyle school, the latter having been found too small to accommodate the increasing number of scholars. It is an encouraging sign of the times—the way the "infant industry" flourishes notwithstanding high tariff, low price of wheat, and questionable freight rates. No matter where one goes, children seem to be increasing and multiplying, and the everlasting cry for "more school accommodation" is joyfully heard by all connected with the building trades, though other taxpayers are inclined to think the industry should be restricted.

The Portage la Prairie School Board have instructed Mr. Browne to prepare plans for three schools, one frame building, to contain one room ; two brick buildings, one to contain two rooms, another to contain four rooms, arranged with hat and coat rooms, and heated with hot air ; cost $15,000.

MONTREAL.

(Correspondence of the CANADIAN ARCHITECT AND BUILDER.)

The new building for the Bank of Toronto, at the corner of St. James' and McGill streets, has just been completed, and the owners have gone into occupation. The building occupies one of the most advantageous site in the city, and Messrs. Taylor & Gordon, the architects, are to be congratulated on having made good use of the opportunity offered by the location for the erection of an imposing and pleasing structure. The building is designed in the Romanesque style and is built of imported red sandstone. The exterior is enriched with a large amount of carving, the credit for the execution of which belongs to Messrs. Holbrook & Mollington, Toronto. The banking room is large, airy, and exceedingly well lighted. The floor is laid with mosaic. The walls, to a height of eight feet, are lined with colored marble, with which the decoration of the upper portion and ceiling is made to harmonize. A very handsome semi-circular counter, in which marble, antique brass, plate glass and grille work have been judiciously employed, is a striking feature. The wood-work is in mahogany. The upper portion of the building has been suitably fitted up for office purposes.

Enquiry amongst architects, real estate dealers, etc., indicates that while the number of buildings to be erected this year will probably fall short of 1893, the amount of money to be expended is likely to equal, at least, that of former years. The new lien act will operate to check speculative building and operations by small contractors, which is not, generally speaking, regarded a misfortune. On this point Mr. Lacroix, the city building inspector, says : "This enactment will result in eliminating a certain number of these contractors, who, without any care as to how they will attain their object, begin a building, not knowing if they will be able to finish it. These contractors cause endless annoyance to the proprietors, the architects, the workmen and the dealers in building materials. If this law causes them to disappear, it will assuredly be so much to its credit." Building for residence purposes will be less in extent than usual, but in character will show improvement, and will be largely confined to the west end of the city.

Some of our local architects have done very little architectural work for several years past, their services having been in demand as valuators in the case of property required to be expropriated by the city for street widening purposes. This work is said to have proved very remunerative, particularly in the case of the city's valuators. One firm of architects are said to have received in fees in one year for work of this kind not less than $20,000.

Among the important buildings to be put under construction the present season are the new Canada Life offices, a French opera house, Laval University, residence for Mr. Hugh Graham, academy at Cote St. Antoine, school building for St. Bridget's parish, and new market buildings.

The union carpenters of this city have gone on strike because of the refusal of the contractors to accede to their demand for a nine hour day at 20 cents per hour. Some of the employers have granted the demand, but the larger proportion have not. The feeling on the part of contractors to whom I have spoken on the subject is that they have less objection to paying the rate of wages asked for than to being subjected to the dictation of the unions as to what men they shall employ. In a word, they object to hand over to the unions the control of their business in this respect. As yet no serious injury has resulted from the strike, but should the difficulty continue much longer, the bricklayers will be forced to stop work. Meanwhile, the contractors are beginning to advertise for non-union workmen. If an understanding is to be arrived at, the present is therefore the most favorable opportunity, as once the places of the strikers become filled, the contractors will be in a less favorable mood to enter into negotiations for this object.

QUEBEC.

(Correspondence of the CANADIAN ARCHITECT AND BUILDER.)

The report of Mr. Chas. Baillairgé, City Engineer, covering the past two years, which has recently been published, contains some information concerning the number and cost of buildings and other improvements constructed during that period, and points to the necessity for the carrying out of other works of like character in the near future.

The number of houses erected during the two years covered by the report is stated to have been not less than three hundred. The total cost of new buildings is placed at $1,841,944. The more important buildings included in this estimate of cost were referred to in detail by Mr. Baillairgé in his article in your New Year Number. This estimate of cost does not include many buildings erected by builders without the supervision of an architect. The value of these is placed at $400,000 additional. As to future improvements the Council are recommended to borrow half a million dollars to be expended on street paving. The use of granite on a concrete foundation is recommended for this purpose.

THE MARITIME PROVINCES.

(Correspondence of the CANADIAN ARCHITECT AND BUILDER.)

For some time the manufacturing committee of the St. John Board of Trade have been endeavoring to induce some gentleman, or company of gentlemen, to erect a pulp mill within convenient proximity to the city. On behalf of the city they offer good inducements in the way of exemption from taxes for a certain period, etc. A few months ago a French gentleman, a manufacturer of pulp machinery, was in St. John. With a number of the leading citizens he visited what were considered to be the best sites for such a mill. He expressed himself as satisfied with the inducements offered him. Since then considerable correspondence has been carried on between the Frenchman and the committee. The former is still willing to expend some $80,000 in a mill, providing the people of this city take a certain amount of stock. The matter is pending now. There would be no difficulty in obtaining a site where a sufficient quantity of wood could be procured to last for many years.

Last summer, and, in fact, the summer before as well, the business portion of Fairville, a suburb of St. John, was destroyed by fire. The citizens are again at work erecting shops, dwellings, etc. Quite a boom is expected there this summer.

When W. C. Van Horne, president of the Canadian Pacific Railway, was in the city a few weeks ago, he was led to consider the advisability of erecting a summer hotel here. He was interviewed on the matter and expressed himself as strongly in favor of the project. He thought an hotel, if erected on very much the same plan as the C.P.R. hotel at Quebec, would not only prove a valuable acquisition to St. John, but that it would be a paying investment to all who should take stock in it. In fact, so favorable was Mr. Van Horne to the proposed scheme, that a number of sites were picked out and the probable cost computed. It was the opinion of the C.P.R. president that a building such as he should wish to see erected for the purpose would not cost less than $500,000. In the first place the hotel would occupy one of the most valuable sites in the city. Its capacity would be sufficient to accommodate one hundred guests. It would be thoroughly furnished and everything in connection carried on on modern and up-to-date principles. A number of the leading business men of the city have volunteered to take stock in the hotel to a considerable extent, and from what has recently come to hand there is every reason to believe that the scheme will not end in talk.

The numerous and expensive buildings which are being run up in Sackville, N.B., this summer has caused quite a boom.

Two new stone quarries have been opened at Westcock, near Sackville, this spring. It is said that those who are interested in the quarries at Woodpoint and vicinity are also at Westcock and endeavoring to get a branch line built to connect with the I.C.R. at Sackville. The present method of shipping the stone on scows to Sackville and from there by rail is very unsatisfactory and the new branch will meet with encouragement.

A. H. McC.

STUDENTS' DEPARTMENT.

C. A. & B. COMPETITION FOR A DRUG STORE.

This is not a very satisfactory competition. The competitors have interpreted the conditions liberally in various directions and have not in spite of this presented as good designs as might have been expected.

"Italia" is without doubt the first. Considering the limited space at his disposal, too much has been made of the dispensary. The space left for customers between the counter and the show window is barely five feet. The second step at the shop door is a serious mistake, and the shop entrance door is too small. The arrangement of the dwelling place and its separation from the shop so as to secure without awkwardness the independence of each, is well managed, and the free communication from kitchen to cellar an excellent idea. But the sizes of the rooms in the dwelling house will not bear too close inspection. An extremely small kitchen is not impossible for use and has even a point in its favour, but an extremely small dining room has nothing that can be said for it, particularly when it is on the wrong side of the house. The dining room should have taken the place of the parlour and been brought out to the hall line. It would then have been sufficiently wide, though still only 11 feet, and would get the eastern instead of the western sun. The parlour would then be the smaller room and we may suppose it a reception room and the dining room to be the family living room. At the bottom of this difficulty is the external centralization of the front windows on the first floor which was quite unnecessary either for an Italian effect or to relieve the beam over the shop window, which latter end indeed is not achieved. The fenestration of first floor should be arranged to suit the rooms inside and then there would be no need of the elliptical windows in which the designer has taken refuge. Had the chimney been placed on the north wall instead of on the east it might have been used to give a better finish to the north wall. "Italia's" design, though it requires a good deal of criticism, is worth criticism. The others are not only less worth criticism but from the scantiness of the drawings furnished with the best of them give less opportunity for it.

Between "Toledo," "Eros" and "Pill Box" it has been necessary to discriminate by a careful comparison of points. As a result it seems best to give the second place to "Toledo" and the third to "Eros."

"Toledo" has placed a good example before him, and though his efforts between the lintel of the shop window and the cornice storey are misdirected the result though defective in design is not offensive to the taste.

"Eros" has managed to reduce the apparent height of his shop window without reducing the light or opportunity of display. In general taste and design he has a slight advantage over "Pill Box" and is therefore placed third.

"Pillbox" makes a neat drawing though in this as well as in his design he is perhaps not following the best examples. His design is at the bottom common enough and he can only get away from it by enrichments which are inappropriate and only land him in bad taste.

"H2 SO4" also deserves mention rather from the neatness of his drawing than from any solid merit in his somewhat showy design.

"Windsor" is strictly commonplace and apparently makes no effort after a truer kind of design.

"Builder" and "Canadian" are too fantastic both in plan and elevation.

The author of the design signed "Italia" which has been awarded first position, is Mr. J. Melville Millar, Montreal. The design signed "Toledo" awarded second position, is by Mr. Walter Siddall, Toronto. "Eros," who has been placed third would oblige by forwarding his name and address to the editor, as it has seemingly been mislaid.—Ed. C. A. & B.]

STUDENTS' NEGLIGENCE.

It has been remarked in connection with the training of our rising architects, and very truly too, that they have not the advantages that their confreres in England have. By these "advantages," generally speaking, is meant, ancient buildings, the use of libraries and a general higher tone of art in all their surroundings, than is possible in a young country. But there is one particular advantage, that by most students, themselves, here, would be regarded as a disadvantage, but which in after years they may come to regret very much they were without in their younger years. It is simply this, that students of professions in England must pay for their education, instead of, as here, being paid while they acquire it.

Let us for a moment compare the ways in which the two systems work. The principal who takes a pupil in England receives a premium, in return for which he gives a portion of his time to the youth and puts within his reach such practical information as he may gather for himself from visits to the works in progress, and again the pupil desires to make the most of his time and to profit by the opportunities put in his way. He does not hesitate to ask for information, because it is his right to receive it, and he is paying for it, and the more questions asked, the more there are to ask, because in no way does the eye of the mind become more effectually opened than by questions.

Here, the principal, who has to pay his pupils while he is trying to make them worth their pay, is placed at an immense and unfair disadvantage. The student, in general, thinks more about his pay than acquiring knowledge, and as has been shown over and over again by our students, do what you will to help them in their studies, not ten per cent. of them show any desire to profit by your actions on their behalf outside their office hours.

Students' Architectural Clubs have been started over and over again by the real, bona fide students ; every one has died an untimely death, and the cause of the decease has not been entirely owing to the departure of their worthy fellows for wider spheres of work and experience. It has been because there were none to take their places, and keep up the weekly meetings —none who would, for their sole advantage, respond to the efforts of the many practising architects who took the trouble to prepare lectures and to go down and deliver them at no small sacrifice to themselves, to the two or three earnest young men bound on progressing, and the empty chairs of a couple of dozen who ought to have been there. Many a time has it been said to these students, "Why do you not ask questions ?" It is not possible, in a lecture, that the subject should be fully explained to every quality of mind in the hearers ; some part or other must require further elucidation to make it clearer to this or that one," and so on, but from our experience, despite all the opportunities given, we might say that at least half of the students who have had these advantages, never asked a single question. Had they had the advantage of paying good round sums for their professional training, we would guarantee they would be more eager to help themselves ; and as to those in the past, so with those in the present, a time will come when they will one and all say, "How unfortunate it is that I was not forced to make more of my time as a student :—daily I neglected opportunities because I did not see the advantages, and was not forced in any way to use them."

The results of the annual examinations bear out the same facts. The majority of the students who present themselves come up utterly unprepared, and instead of the majority passing, it is the minority only who are successful. We would warn students that these are days in which only the thoroughly proficient can make even a living out of his profession ; the competition is overwhelming ; he who starts on the battle of life unqualified must succumb, and if he does, he has only himself to thank or to blame. It is to be feared that few of the present generation of students will make any mark in the world when they go out from us, and as long as they work only for their pay, there will be little improvement in the race.

INTERCOMMUNICATION COLUMN.

This column is intended to afford a means of correspondence for students, builders and all our readers desiring information they cannot otherwise obtain. Questions for which an immediate reply is required should be marked "Urgent." Names and addresses of correspondents must be sent with their communications, but these may be signed with initials or otherwise for publication.

QUESTIONS.

[19]. I should be obliged if you could tell me the strength of wire ropes as compared with ordinary hemp ropes. I notice that contractors in town use wire ropes a great deal in large buildings for guys and such purposes.—"Country Builder."

REPLIES.

[14]. "Aspirant,"—You might carry up your column to a height of 700 ft. with perfect safety. Average sandstone weighs about 145 lbs. per cubic foot and would require a vertical column of 4158 ft. high to crush the base stones, but they might crack under a column about half that height. It is safer not to trust to more than 700 ft., or from one-sixth to one-tenth the crushing height.—"Science."

[16]. "Frosty,"—The weight of snow, fresh fallen, is from 5 to 12 lbs. per cubic foot. A cubic foot of water weighs a little over 64 lbs. "Frosty" can therefore see, that if his snow will lie until it thaws, and his roof has to support water, he must allow for an increase of weight of from 50 lbs. to 57 lbs., according to the depth of the snow water likely to stand on the roof. For ordinary purposes, for snow moistened and compact by rain, allow from 15 to 20 lbs. per cubic foot.

[17]—"J. L. T."—Trautwine (Edit. of 1886) p 397, gives a description of the making of a sun-dial. It is too long to give here, but if you cannot get hold of the book we will endeavor at some future time to publish it.—[ED. INT. COL.]

[18] "Predicament."—We should require further particulars before we could answer your question. Your site is unusual, therefore a general answer would not suit your case. Let us know the kind of building you intend to erect, and also give a more detailed statement of the nature of the clay.—"M. P."

The following students were granted certificates of proficiency in architectural drawing at the recent examinations of the Toronto Technical school :—W. Bell, J. Michael, C. McPherson, W. R. Bale, E. Stanton.

THE HARMONY AND FUNCTIONS OF COLOUR IN ART.*

BY ANDREW T. TAYLOR, F.R.I.B.A.

(*Continued.*)

These results would be somewhat minimized and modified if you divided the colours from each other by broad lines of black or white or colours. You will find also that if your colour is put on a white ground the colour will be stronger than if you put it on a black ground, because in the case of the white ground it tends to overpower the extra white rays given out by the colour, and in the case of the black ground the extra white rays given out by the colour are increased by those reflected from the black ground.

All this is but the alphabet of colouring. You will find that there are numberless gradations of hue and tint and shade of colour, and on your perception of these and skill in using them will depend your refinement of colour. Many never get beyond the use of the primaries and secondaries and perhaps one or two tints of the tertiaries, while between white and any of the primaries a skilful colorist might make a hundred different shades.

In nature the colours of shadows are always in contrast to their lights, and of positive hues with negative shades; accordingly you find that coloured back-grounds shew out white sculpture best; of these blue is one of the best colours from its affinity with shade, and we know that the Greeks used this a good deal in their back grounds for sculpture, etc. So gold, being in close relation to light, is good for dividing up colours and very useful in decoration, and will go with any colour. This is the reason it is used so much for frames for pictures.

The subject of colour blindness is worthy of attention; and many more persons are either colour-blind or have imperfect colour vision than is generally supposed. This is a very important matter in its bearing on railway officials and employees, as often the safety of carloads of passengers depends on the engineer's correct observation of the colored signals. In France it was found lately that over 9 per cent. of the railway officials were color blind.

The commonest defect is an imperfect impression of red, and many persons can see no difference of *colour* between a scarlet geranium and its green leaves, but only a slight difference in tone. You can see how this would affect an artist for example in the mixing and laying on of his colors, or a salesman in matching ribbons and silk, and other fabrics.

It will be useful to us to know something about the colours of which we have been speaking and which some of you may be indeed using.

A knowledge of his pigments is most important to an artist. Many of the failures of pictures and their grievous change for the worse in a few years after they were painted, are due to this want of knowledge. Both Sir Joshua Reynolds and Turner were great experimenters in colors, and sometimes sacrificed safety and permanence to attain brilliancy and a particular effect. There is no doubt that many oil paintings have altered very much from this cause, and others from successive coats of varnish laid on with intermediate layers of dirt, until what we see now as works of the great masters are often but caricatures of what they were originally. Also with water colours. Recently there was quite a journalistic war as to whether water colours were permanent or faded, and I think there is no doubt that it was conclusively proved that many water colours had undergone material change by exposure to light and especially to strong sunlight, and that certain colours were more evanescent than others.

In colours for the palette you should only use those which possess the following qualification—purity and brightness, body, or on the other hand, as the case may be, transparency, and above all, durability. There are very many beautiful colours, but the necessity of the above qualifications restricts the number to comparatively few. But this is not to be regretted; the tendency is to use too many colours. Many a fine picture has been painted with only three or four tints, and Henner often paints pictures which are lovely in colour and feeling with but three colours. The more you mix colours the muddier you are apt to get them and the more difficult it is to keep purity of tone.

Although White is not properly speaking a colour, yet it is an important pigment, as it enters into nearly all the other colors and is much used in combination in oil painting and in tempera, as it gives light and vividness, as well as easy toning down. White lead is the base of most of the white, and has this defect that it is apt to turn black in time and injuriously affects some colours. Zinc white is durable, but wants the body and brightness of white lead.

For water colour Chinese white is mostly used. It is a preparation of white oxide of zinc mixed with gum arabic, glycerine, etc., and especially in body colour work, is most valuable.

The primary colour Red is, as we found, the most positive of colours. Being so, it is somewhat difficult to manage, and has to be used very sparingly. If you will notice, a touch of red here and there in a picture will brighten it up, and draw attention to itself in the most surprising manner. Nature uses red with very great reserve, and when used, takes great care to tone it down with green or other soothing colour.

Vermillion if of the genuine kind is a good durable colour, and has great body and weight, but for this reason you will find it will not readily mix with other colours.

Indian Red is brought from Bengal, and is an iron ore or peroxide of iron. It is permanent and very opaque.

Light Red is a brown ochre, burned, and is very useful for flesh tints and in landscape.

Lake is a very transparent pigment, and is of several kinds. The scarlet lake is obtained from cochineal, and washes well; it is, however, liable to fade in strong light.

The carmines are also obtained from the cochineal, and work well, but are liable to fade in strong light, and are not permanent with white lead.

Blue is the coldest and most retiring of the primaries, and cools and tones down all colours with which it is in combination.

Ultramarine is perhaps the most beautiful blue that we have, and is prepared from the lopis lazuli, a precious stone found in Persia, etc. It is very transparent and pure, and has great brilliancy and permanency. It is largely used for skies. Unfortunately it is often adulterated, its costliness being a strong temptation.

Cobalt is prepared with metallic cobalt or its oxides, and is next to ultramarine in its brilliancy, and in water colour, works even better than the other. It is permanent so far, but is affected by time.

Prussian Blue is formed from prussic acid, iron and alumina, and is a deep and strong blue of great body and transparency.

Indigo is got from plants in the East and West Indies; it is also very powerful and of great body and is transparent. In mixture with white lead it is fugitive and is not so reliable as Prussian blue.

Yellow is the remaining primary, and is the nearest to light; in varying tones it is much used in nature. It is akin to gold, and was often so used in old manuscript.

Chromes are a modern discovery, and are mostly chromates of lead. They are brilliant and beautiful, but are not safe colours, as after a time they lose their purity and become dull and heavy. They are also injurious to some blues when mixed.

Naples Yellow is a compound of oxides of lead and antimony, and was originally prepared at Naples, hence its name. It is a pleasant warm tint, is opaque and covers well, and in an oil medium is permanent and good, but will ultimately change its colour, in water colours, and must not come in contact with oxides of iron of any kind.

Yellow ochre is a native pigment found in most countries.—The ochres are very useful and practically permanent.

Raw Sienna is an iron ore, but it is very useful and is transparent, and best of all, is permanent.

Cadmium Yellow is prepared in different shades and is a strong, light, pure useful colour; it is prepared from the metal cadmium, by precipitation with solution of sulphuretted hydrogen. It is permanent and good.

Gamboge is obtained from certain trees in India, and is of a gummy resinous nature. It is a bright, transparent, delicate yellow, and is exceedingly useful, not being affected much by sunlight or impure air, but it does not show in gaslight.

Indian Yellow has been long used in India, and is a beautiful, pure yellow, but it is not lasting, and in oils is very fugitive; it has a very strong unpleasant smell, and is not a safe colour.

We will not for the present take up the secondary and tertiary colours, as they are in large measure products of the primaries, and the subject is too large to treat properly just now, but rather go on to look at color as illustrated in painting, architecture and sculpture, and first of painting.

All painting was originally a hand-maid to architecture, that is, was employed to beautify parts of a building, and was incorporated as part of the same in fresco and tempora work, and therefore, being painted for, and actually at a particular spot, its colour was made to harmonize with its position. The modern pictures, or, as we would say, easel pictures, are much more recent, and being intended to hang anywhere, are governed by no such restrictions, but have each their own key of colour, independent of everything else. It is this that makes a modern picture gallery so confusing and tiring. Every picture is out of sympathy and tone with its neighbor, and if by very skilful hanging this is in any way modified, it can never be wholly got rid of. This is also true to a certain extent in our houses; pictures are bought and hung on our wall which are out of touch and tone with their surroundings—whether it be the furniture, the hangings, or the other pictures—and consequently there must be a certain amount of incongruity. What we call oil painting was practically not known, at least in its modern form, until the beginning of the 15th century. When the brothers, Van Eyck, the Flemist painters, may be said to have discovered it. Nearly all the work done previously to that time was in distemper, and therefore more suited to permanent positions on the walls of churches and other buildings.

Vasari tells us that Jan Van Eyck, who delighted in alchemy, set himself to try various kinds of colours and oils to make varnishes, as artists at that time knew of no way in which pictures on panels could be made durable, and could be washed without losing colour. He made many experiments and at last found that oil of linseed and oil of nuts were the best for drying. He also saw that when the colours were mixed with these oils, not only were they safe from injury by water, but the colours also had more lustre, and the colours blended better than in tempora. The fame of this invention soon spread in Flanders. Even the Flemish artists endeavored to keep the secret of oil painting, and it was not until later that it was known in Italy, and stories are told of Venetian painters disguising themselves and going to Belgium to try to learn this secret. One Antonello, of Messina, was so struck by a picture in oils that had been sent from Bruges to the king of Naples, that he set off for Belgium, and by dint of giving Jan Van Eyck numerous presents and flattering him, he got the secret, and returning to Italy, settled in Venice and painted many pictures in this new method, which could be kept secret no longer, and was rapidly adopted by other artists.

Painting upon the walls had certain advantages; it could not be carried off so readily as an easel picture, nor without risk of ruining it. It is said that the king of France tried hard to get the "Last Supper" of Leonardo da Vinci, which he painted for the friars of San Maria delle Grazie at Milan, transferred to France, but the risk was too great, and it has remained in position ever since, although now but a wreck of its former self. It is pleasant to find the estimation in which great art was held at that time, for we are told that another picture that Leonardo painted about this time, at Florence, was so good that his rooms were filled for days with crowds of people going to see his works as to a solemn festival. And the story of Cimabue's Madonna is well known, how it was considered such a marvellous thing that it was carried through the streets in joyful procession to the Church of S. Maria Novello, where it still is, and when King Charles of Anjou was entertained at Florence, a sight of this picture was considered a very important part of the programme. Would that this love and appreciation for art was as general now as then—Art would need no other stimulus.

As soon as painting in the medium of oil became known, a great change came over the character of the works; the scope of subjects became greatly enlarged; mythology, ancient and current history, classical story were drawn upon, and a great impetus was given to painting generally. Greater richness of colour was attained than was before possible with tempora.

In landscape painting, as in all painting, it is of the first importance that we preserve the clearness of our colour, as has been said by a living artist: "Good painting is like beautiful language, it must express briefly, clearly, forcibly, our meaning; each finishing touch in a picture should be considered like one word in a sentence; to put a number of touches where one ought to suffice is like stammering in painting."

We come now to colour in *Architecture*, and here the same laws of harmony govern as in painting, but being on so much larger a scale, and viewed in connection with the surroundings of nature, the scheme of colour must necessarily be on a much broader and simpler key. Under the sunny skies of Italy they revel in the most beautiful colours on the outside of their buildings, which present a continual feast for the eye of the beholder. The Duomo at Florence and the older Baptistry are glorious in colored marbles, and not a little of the indescribable beauty and loveliness of Giotto's Tower there, is due to its color as seen under soft Italian skies. St. Mark's at Venice, both inside and out, is rich in coloured marble and gold mosaics, mellowed by time into beautiful hues.

It is interesting to know that in all ages, and amongst all peoples, polychromy has had an important place in architecture. Hittorph, in his investigations in Sicily and the Acropolis Selinas and other temples, and recent investigation in Greece, has abundantly proved the liberal use the Greeks made of colour on the exterior of their temples, etc. The custom also prevailed extensively all over France in the middle ages and during the Renaissance, but gradually declined in the reign of Louis XIV. Viollet le Duc, the late eminent architect and antiquarian, made a careful examination of Notre Dame Cathedral at Paris, and found unmistakable evidence that a large portion of the facade had been radiant with colour, and even in England many of our cathedrals there show also remains of colour, but the climate has dealt too rigorously with them to leave much evidence. Somehow when we took to borrowing Roman Orders and Architecture, both in

*Paper read at a meeting of resident members of the Province of Quebec Association of Architects, at Montreal.

England and France, the forms only were reproduced, and the original glittering roofs and mosaic and marble work were forgotten. Increased knowledge on this matter has led of late to colour being much more extensively used, especially in Paris, as in the Opera House, the Hemicyle, the Beaux Arts, and many modern buildings.

Somehow, in northern countries, under dull gray skies and lowering clouds, form was developed largely to the exclusion of colour, and that in the very face of nature's example, for we have only got to leave a building alone and time will soon beautify it with pearly and emerald lichens and mosses, and touch the stones and roofs and timbers with harmonious tints, such as the ruins of castles in Britain and Europe everywhere show. Even here nature will do her best if we will but let her. The monotony and dullness of the average streets of cities are very depressing, especially in manufacturing cities, where we find rows on rows of dirty soot and smoke begrimed houses.

Some years ago, in London, the average fashionable house had a dingy colored compo-cement front, and the back was too dreadful to think of; then there came a revulsion, and armies of painters appeared, and lo! the fronts of the houses blossomed out in claret color, and sage greens, and blood red, and mustard yellow, and other colors hard to give a name to, and although in some cases presenting a somewhat incongruous and piebald appearance, were yet infinitely better than the old. The next stage was better still, that of using honest material of natural pleasing colour, which would withstand the smoky atmosphere. So terra cotta and tile work and warm colour tone were and are used.

Surface applied painted work will not do, but the use of coloured materials themselves seems to be the line on which we shall achieve greatest success.

In New York there was a brown stone period, when a man could not shew himself in society unless he lived in a brown stone house, and so streets and terrace of brown stone still chill our sympathies. New York had also its white marble period, when to live in a white marble house was considered the acme of bliss, and so leprousy looking erections took courage and reared their heads in the streets. Now more pleasing arrangements of material and colour are in vogue—red brick and red stone and warm cream colored stone meet the eye in all the newer quarters, and in combination with the green of the trees and grass, present very pleasing pictures. And to come nearer home, a cut gray limestone house was considered amongst ourselves as the sign of eminent respectability, but fortunately of recent years, red brick and terra cotta and red and buff stone, have been largely employed, alone or in combination, and I cannot but think to the beautifying of the city and the advantageous breaking up of the monotony of our streets.

In more genial and equable climates, where the houses are ugly and commonplace, they are often redeemed and made even beautiful by a veil of green ivy growing up to the top, or by Virginian creepers, or by balconies and window sills full of plants and flowers. It is surprising how a few bright flowers on an outside window sill will brighten up a whole front of a house, and give pleasure to every passer-by. Here it is only in summer that we can attempt such a thing, and alas, the ivy is not available to cover the ugliness of some of our houses. We do not want the exterior of our houses to be like harlequins, but neither do we want them to be like quakers or Gray nuns. We should take a lesson from nature, who never is in monotone, and even where you fancy she is, on closer inspection you will find it made up of a large variety of hues, but all in perfect harmony.

Oriental art differs essentially from ours in its bright melody of colour; they use colours externally of a richness and brightness that would make our hair stand on end, yet always with harmony, congruity and beauty. We cannot, in our climate, use these in such richness or wealth, yet we can and ought to use the softer shades, which have depth of colour without garishness.

So far so good, but possibly some of you may say, "Now coming to sculpture. You surely no not advocate colour in sculpture." And yet if you think, why should one important branch of art be robbed of the charm of colour, and have to depend entirely on beauty of form? It is largely a matter of habit that we have come to expect sculpture in white marble, or else in bronze, which speedily turns black. It seems to suit our matter-of-fact minds, and this matter-of-fact age, that we must have even our sculpture in "black and white," reduced, as it were, to legal exactness.

It was long thought that ancient sculpture was not coloured, but it has been placed beyond all controversy that the Greeks, who were the best sculptors that the world ever saw and will possibly ever see, employed colour to heighten the effects of their sculpture, and never hesitated to cover even the most precious white marble with gold and blue and other colours. Careful examination of many of the sculptures of the Greek temples conclusively proves this, as the remains of the colour is very plain. There is no doubt that the famous Parthenon frieze was colored, and quite recently several sarcophagi were found at Sidon, three of which are Phoenician in character and seven of Greek design of the purest type, without a trace of Roman influence, richly sculptured, and bearing close resemblance to the Parthenon frieze in the horses and beauty of the figures. These show large remains of colored decoration, and leave no doubt whatever as to great development of Greek polychromy in their sculpture, as well as in their architecture. So also the Christian sculpture and Gothic art. There are numberless examples in our cathedrals and old mediaeval buildings of sculpture, both of the figure and of natural forms, with more or less remains of rich colour upon them, on the portions less exposed to the weather than the others. And where we find Greek sculptors and the best Gothic sculptors employing colour in their sculpture, the abstract theorical use of it cannot be condemned. It is in the application of it that we are apt to go wrong. Here very great caution and artistic sense has to be exercised, and Gibson's tinted Venus stands as a warning that there are defined bounds and limits to its application. There are certainly great objections to the use of natural colour in isolated figures, subjects either wholly or partially draped, in that the colour takes away from its ideal and abstract character, and it becomes at once an imitation of a living person, and as such, influences us in quite a different way.

The modern fashion of placing busts about the middle of a room is hardly in the best taste, and isolating sculpture out of its proper sphere, but where it is rightfully employed to heighten the effect of a building and such like, then the necessity for the use of some material of such a colour as to harmonize with the building arises. More especially where isolated statues are placed in our streets to commemorate some noble life or deeds; if they are of white marble they get grimy and streaky and dirty, and the light and shade is crude and hard. If they are of bronze, they speedly become black as a negro, obliterating all the finer lines of expression and fold of garment, and presenting little more than a silhouette against the sky. In one notable case, that of the statue of the Prince Consort in the Albert memorial, in Kensington Gardens, London, a bold departure was made and the statue was gilded all over, but the result was no better than before, and indeed, rather worse, and was christened the "God of Mammon."

I would just mention the beautiful majolica or faience work of Luca della Robbia, which glows from so many of the facades of the Italian churches. They were chiefly figure work of a religious nature—Holy Families, Virgin and Child, Saints, etc.—but so beautifully modelled, and such rich colors burnt in and glazed so as to be almost imperishable—a very suitable material for smoky atmosphere when they could be washed and always keep their brightness and beauty. The secret was so well kept by the Robbia family that it died with them, and we have been unable to get the full brilliancy of all the colours, but a resuscitation of this in some such form would seem to fulfil the conditions of modern times.

I had intended to speak of colour in interior decoration, but it is so large and important a subject that it is worthy of a better place than the close of a paper, and I will conclude in a word by respectfully urging you all to assiduously cultivate your colour sense in the conviction that it will minister to your susceptibility to refined and beautiful impressions, and afford an abiding source of joy and pleasure.

USEFUL HINTS.

To clean marble mix up a quantity of the strongest soap lees, with quicklime, to the consistence of milk. Lay the mixture on the marble for twenty-four hours, then wash it off with soap and water, and repolish if necessary.

TO PRESERVE SCAFFOLD ROPES, ETC.—Ropes used for scaffolding may be preserved by dipping, when dry, in a bath containing three-fourths of an ounce of sulphate of copper to a quart of water, and kept in for four days; then hung up and dried.

All main steam pipes and steam risers says the Heating Engineer, should be connected at their lowest levels by relief pipes run to or connected with the main return pipes, or to the return risers below the water line in the boiler, to take from them any condensation that may be formed. These relief pipes also serve to equalize the pressure throughout the apparatus, or the return lines may all run below the water line of the boiler, in which case the connecting lines spoken of are unnecessary.

TO REMOVE CREASES IN DRAWINGS, ETC.—Fasten the engraving or drawing by drawing pins on a board face downward on a sheet of paper. On the back place another sheet of paper which retains a very slight quantity of moisture. Over this place flannel or blotting paper, and taking a hot iron pass it carefully over the part where the creases have been made until they disappear, and then submit the drawing or engraving to pressure between glazed boards.

Mr. Thos. Potter in a letter to the Builder, states that the better concrete is the more readily it conveys sound, and that an actual trial lately proved that ordinary conversation could be distinctly heard through a six inch concrete wall plastered on both sides, and the same applies to concrete floors. Such floors should never be constructed solid throughout, says this writer, if required to be sound-proof, and where wood in the form of joints, bears directly on the concrete, sound is very readily transmitted from one to the other.

TO GILD ON PLASTER OF PARIS.—To satisfy the absorbent nature of the plaster, brush it over with linseed oil, at intervals of twenty-four hours, till it will absorb no more. Then go over it with oil gold size, ground with yellow ochre into a paste. If this size does not work freely, thin it with linseed oil. When this is so far dried as to be just tacky, gild in the ordinary way with gold leaf, using a tip. Press the gold gently but firmly down with a bob of cotton, covered with soft washing leather; then rub off superfluous gold, and smooth the surface with a second bob of cotton not covered.

One of the latest things in the way of so-called fire-proof material for building purposes is "metal plated lumber," the invention of a Baltimorean. The method pursued is to take a piece of lumber of any desired shape or length, together with a strip of thin sheet metal to correspond, and run them through a simple machine, formed mostly of rollers, which folds the metal skin tightly around the lumber. Thus prepared, it is claimed that the lumber is specially adapted for use in the construction of doors, flooring, partitions, stairways, freight and passenger cars, granaries, refrigerators, &c., &c.

The following weights for brickwork in mortar, 100lb. per cubic foot; brickwork in cement, 112lb. per cubic foot; masonry, rubble, 140lb. per cubic foot; masonry, ashlar, limestone, 150lb. per cubic foot; masonry, granite, 160lb. per cubic foot, are after Rankine. The following weights for timber are due to Haswell:—

	Weight of cubic foot. Green.		Seasoned.	
	lb.	oz.	lb.	oz.
American pine	44	02	30	0
Ash...	58	3.	50	0
Beech	60	0	53	6
Cedar	32	0	28	4
English oak	71	10	43	8
Riga fir	48	12	35	8

But no definite rule for correctly calculating weights from the measurement of timber can be given, for Rankine, in "Civil Engineering" (Griffin, 1870), states that the timbers given below have the percentage of loss of weight in seasoning set against them. The correct weight per cubic foot depends then to a great measure upon the condition of the timber: Red pine loses in seasoning twelve to twenty-five per cent. in weight; American yellow pine loses in seasoning eighteen to twenty-seven per cent. in weight; larch loses in seasoning sixteen to twenty-five per cent. in weight; British oak loses in seasoning sixteen to thirty per cent. in weight; elm loses in seasoning about forty per cent. in weight; mahogany loses in weight sixteen to twenty-five per cent. in weight.

CORRESPONDENCE.

[Letters are invited for this department on subjects relating to the building interests. To secure insertion, all communications must be accompanied by the name and address of the author, not necessarily for publication. The publisher will not assume responsibility for the opinions of correspondents.]

THE NECESSITY FOR A CANADIAN SCHOOL OF ARCHITECTURE.

MONTREAL, May 3, 1894.

Editor CANADIAN ARCHITECT AND BUILDER.

THE Province of Quebec Association of Architects and the Ontario Association are endeavoring to do good work in the the face of the craze for Americanism that has been the rage in Canada for a few years back. They have formed associations for the culture of artistic architecture, and especially aim at courses for the students, and only wait the munificence of some of Montreal's benefactors, who have been so liberal to the other arts. We understand that space is available in the applied science department at McGill, and only requires the appointment of competent professors to start a school of architecture equal to Cornell or the Boston school. If this could be accomplished, our young men need not seek architectural training in the United States. This, I contend, is the root of all the evil. How can it be otherwise, as is rightly argued by wealthy capitalists, who seek the latest and most advanced ideas in art and architecture. A school of architecture would place all the exalted ideas, present and past, before the student's mind. His eye would be trained to the beautiful in art, his mind would be stored with the best of all the ancient examples, the theory, the styles, the proportion, the strength, construction, designing, and correct and artistic principles would be instilled as the alphabet is in a child—never to be forgotten. Everything that is pure and noble in architecture would become a part of every student of ability, and in obtaining his diploma the public would be assured that he at least knew something about architecture, and that it would be unnecessary to go to foreign countries for taste and ability. The case is now deplorable. All our large and expensive buildings are given to Americans, and to some without this special training. And what has been the result? In our own city we have examples of the failures in design and construction. The Y.M.C.A. is in a deplorable state, and in a few years may become a complete wreck. Other examples in Toronto are fully as bad, and in the face of this, still our Canadian people will persist in employing this foreign talent. The latest insult our Canadian architects have had to submit to is from the Canada Life Assurance Co., a purely Canadian company! making its revenue out of Canadians, its chiefs Canadians, and yet it employs an American, and gives him carte blanche as to expense—some $400,000—to spend on a comparatively small building. A Canadian would have been asked to build this palace with $150,000, at most, and comparisons would be made with American buildings costing half a million.

This is not all. This new building is to be erected alongside the Temple Building, and on a mean technicality the Trustees of the latter building are asked to take down the rear portion of the party wall, the claim being that it was not according to law, while they acknowledge that if it was, it would still be insufficient for this new fire proof building, which is to be three stories higher than the Temple.

They appear to be using all the smart dodges they can invent to misrepresent the actual thickness and strength of the wall, and try to induce the City Inspector to condemn said wall, but thanks to the City Inspector's practical and extended knowledge, he refused to do this, and states that the wall is good and sufficient for the Temple, it having stood without a hair's breadth of settlement, and remains just as it was built, five years ago.

For a wealthy Canadian company to allow itself to be placed in such a doubtful position is not to its credit. The City Inspector, when he granted his certificate to the Trustees of the Temple building, knew what he was doing, as is amply proved by the stability of the wall. He knew full well that the lower part, 2 ft. thick for two stories and sixteen and then 1 ft. of an old wall, thoroughly well built, with the best 1½ thick brick and good mortar, equal to cement, was as good as a new wall 4 in. thicker, and so would any practical architect decide, with the exception of an autocrat American, in whose hands our Canadian companies appear as so many puppets.

If, as I said before, our young men were thoroughly trained, our Canadian public would have the guarantee that all receiving the diploma would at least be men of knowledge in the profession, and would attain as high a standing before all the world as do our doctors and lawyers.

CANADIAN.

LEGAL.

The Supreme Court of the United States has decided that where carpenters are employed in a building and no notification of the fact is given by the owner to the insurance companies holding risks on the building, as provided for in the conditions of the policy, the validity of the policy is thereby rendered void.

Mr. C. R. S. Dinnick has lately added to his brick making plant at Toronto Junction a wire cutting brick machine with table and die. A similar machine has been purchased by the Burlington Pressed Brick Co., Freeman, Ont.

ARCHITECTURE AT THE MONTREAL ART GALLERY.

Editor CANADIAN ARCHITECT AND BUILDER.

SIR,—The annual spring exhibition of oil and water colors with the usual adjunct of a few architectural drawings is now the chief attraction at the art gallery, and it may be said that the exhibition as a whole, compares favorably with those of former years.

To an architect an exhibition of this character should prove particularly interesting, and the idea of combining an exhibition of architectural drawings in one which includes other works of art, is about the only way at present to advance the cause of good architecture in a city like Montreal, for the chances are that an exhibition that was purely architectural in its character, would very likely prove a failure, for the reason that the public for the most part does not as yet regard architecture as an art, and what is worse, thinks that an architect's calling is one that can be equally well filled by a novice, as by an educated practitioner.

It is not the intention of this article to enter upon a detailed criticism of the drawings on exhibition, but it is my firm belief that an exhibition of architectural drawings is valueless as a means of educating the public to know what is good and what is bad without fair and just criticism. Our architects as well as the public should be willing to invite the criticism of their work by those who are competent to judge, as such criticism not only points out to us our errors which we ourselves are only too apt to overlook, but it tends to broaden our ideas and incite us to make still greater efforts to improve the quality of our works, which ought to be the great object of every architect who has the cause of good architecture at heart. Any one who has read the comments in our daily papers on the exhibition will find that the works of our local artists for the most part have received their fair share of criticism, but scarcely a passing notice is given to the architectural drawings. Why is this? Is it because our local art critics think that an architectural design is something outside the sphere of art, or is it because they are afraid to take up the matter owing to lack of knowledge? If it is owing to the latter, what a lamentable state of affairs then exists, and which only can be rectified by time and proper training.

A knowledge of art is a very excellent and a most desirable acquisition to one's education, and good art has always exercised an elevating and refining influence upon individuals as well as nations, and as we are a very ambitious people, and wish to be considered a refined and cultured people as well, it is only natural and proper that we should patronize art. But in order to become an artistic people in the fullest sense of the word we must be educated in art, for, unfortunately, although we are lovers of the beautiful, we are not naturally an artistic people; we look altogether too much at the utilitarian side of things, thinking that as long as anything answers its purpose it does not matter whether it pleases the eye or not: It is this state of affairs that must be remedied, and the only way to bring about the much desired reform is by educating the public. Of all the arts that we should know something about, it would seem only natural that architecture, that art above all others, is the one where we should make the starting point, for the reason that it is an art that had its beginning before all other arts, and one that administers most largely to our comforts.

Buildings that are well designed and beautiful in proportion and detail are the surest evidence of a nation's wealth and culture, and have been so from time immemorial.

How this much desired change is to be brought about is an important question, but one way of doing it would be to have architecture taught in our public schools, and perhaps some day in the near future some of our wealthy citizens may see their way clear to establish a school of architecture in connection with one of our great collegiate institutions where those who wish to practice the architectural profession can receive the proper training. Then, and not until then, will architectural art assume the position among the arts that it should, and greater inducements will be given members of the profession to exhibit their work when they feel that their efforts will be appreciated by the public.

ARCHITECT.

RECENT CANADIAN PATENTS.

A patent has been granted to Mr. A. Wilford, Todmorden Ont., for a brick kiln, comprising in a continuous kiln, a series of independent adjacent chambers with horizontal walls between and the chambers connected to each other by horizontal passages, and each chamber being provided with draft openings to supply a current of atmospheric air to the fire within, means for supplying fuel to the fire, a flue for conveying the heated air from one chamber to another, etc.

H. Johnas Johanson and Bertrand Harris Short, of Vancouver, have patented a paint for iron, etc., composed of tar, salt, carbon bi-sulphur, benzine refined and paraffine cake.

John Geo. Heilig, Hamilton, Ont., has patented a ladder shelf scaffolding.

A patent for a sash fastener has been granted to Mr. L. Eveland and Alonzo Herrick, of Port Stanley, Ont.

Robt. Sampson, Quebec, has secured a patent for a plumber's test pump.

ROUGH-CASTING IN CANADA.

ROUGH-CASTING, or as it is sometimes called, slap-dashing—both words of which are synonymous with the French *hourdage*, rough work, and *ravalement*, having a similar meaning, writes Mr. Fred. T. Hodgson in Architecture and Building—is a method of plastering the outside of buildings much used in the northern part of Canada, because of its being durable, cheap and well adapted to keep out cold winds during our long winters. The methods of applying rough-cast and the mixing thereof do not materially differ from the methods adopted in Northern Europe or even in the North-Western States, but it is these minor differences, perhaps, that make the rough-casting done in Canada superior, so far as durability is concerned, to much that is done in other parts of the world.

There are frame cottages near the city of Toronto and along the northern shores of Lake Ontario that were plastered and rough-casted exteriorly over forty years ago, and the mortar to-day is as good and sound as when first put on, and it looks as though it was good for many years yet if the timbers of the building it preserves remain good. Rough-cast buildings are plentiful in every province in the Dominion from Halifax to Vancouver and from Lake Erie to Hudson Bay, and when well built, and the rough-cast properly mixed and properly applied, the result is always satisfactory. It is quite a common occurrence in Manitoba and the North-west territories in the winter to find the mercury frozen, yet the intensity of frost does not seem to affect the rough-casting in the least, though it will chip bricks, contract and expand timber and render stone as brittle as glass in many cases, and the effect on iron and steel is such as may prove dangerous if exposed to sudden and unexpected strain.

In preparing a frame or log building for rough-casting, care must be taken in putting down the foundation. A good stone or brick foundation is, of course, the best, but where rough-casting is intended, stone or brick foundations are seldom used because of their cost, and the builder is compelled to use posts of wood. Here the posts are generally made of white cedar, which has a lasting quality of thirty-five or forty years, if sound when used. The posts are put in the ground from 3 to 5 feet, the deeper the better, as they should be deep enough in any case to prevent the frost from forcing them upward. When a sufficient number of posts have been properly placed a line is struck on them the proper height from the ground and the tops levelled off. The sills are then placed—all joints being broken on top of posts—and the whole made level. These sills and all the other timber, scantlings and lumber, should be well seasoned, if possible, for the greatest enemy to the plasterer is unseasoned timber; shrinkage of joists, posts and scantling, not only breaks the bond of the mortar, but causes great cracks in corners and angles, that no amount of pointing or patching can ever make good.

When the frame is up and the rafters on and well secured, the whole of the outside should be covered with good, sound, common inch stock pine, hemlock, spruce or other suitable lumber, dressed to a thickness. If put on diagonally so much the better, but this is not absolutely necessary if the rough-casting is to be of the best quality, as will appear hereafter.

When it can be done it is best to get all partitions set in place and lathed, the roof on and all necessary outside finish or grounds put in place and made ready to receive the lath. The carpenter must prepare his finish or grounds for finish to accommodate the extra lath, as the walls will be thickened accordingly.

For the cheaper sort of rough-casting in one or two coats, the following method of lathing is employed:—Nail laths on the boarding—over paper or felt, if paper or felt is used—perpendicularly 16 inches from centre to centre if 4-foot laths are used, or 18 inches or 1 foot from centre to centre if 3-foot laths are used. The whole surface to be rough-casted will require lathing this way. When done lath as is ordinarily done with No. 1 pine lath, breaking joints every 15 inches. Put five nails in each lath, driving each nail home solid, coat over with mortar, well haired, and that has been made four or more days, smooth and straighten as well as possible with a darby. When done and while yet soft the rough-cast is thrown on it with such force as to drive the pebbles or small stones deep into it. The mixture or dash, as it is called, is composed of fine gravel, clean washed from all earthy particles and mixed with pure lime and water till the whole is of a semi-fluid consistency. This is mixed in a shallow tub or pail and is thrown upon the plastered wall with a wooden float about 5 or 6 inches long and as many wide, made of half-inch pine and fitted with a wooden handle. While with this tool the plasterer throws on the rough-cast with his right hand he holds in his left a common whitewash brush, which he dips into the rough-cast and then brushes over the mortar and rough-cast, which gives them, when finished a regular uniform colour and appearance.

For this sort of work the following proportions will answer: To one barrel of prepared gravel use a quarter barrel of lime putty; mix well before using. This may be coloured to suit the taste by using the proper materials, as given further on. It must be understood that the foregoing is the cheapest sort of rough-casting, and is not recommended where more durable but more expensive work is required.

The best mode of doing this work, as practiced in the lake district of Ontario, is about as follows:—Have the frame of building prepared as indicated in the foregoing, with partitions all put in and well braced throughout and well secured. Lath diagonally with No. 1 pine lath, keeping 1½ inches space between the lath. Nail each lath with five nails and break joints every 18 inches. Over this lath again diagonally in the opposite direction, keeping the same space between the lath and breaking joints as before. Careful and solid nailing is required for this layer of lathing, as the permanency of the work depends to some extent on this portion of it being honestly done. The mortar used for the first coat should have a goodly supply of cow's hair mixed in with it, and should be made at least four days before using. The operator must see to it that the mortar be well pressed into the key or interstices of the lathing to make it hold good. The face of the work must be well scratched to form a key for the second coat, which must not be put on before the first or scratch coat is dry. The mortar for the second coat is made in the same way as that required for the first coat, and is applied in a similar manner, with the exception that the scratch coat must be well damped before the second coat is put on, in order to keep the second coat moist and soft until the dash or rough-cast is thrown on. The rough-casting is done exactly in the same manner as described for the cheaper sort of rough-cast work.

A building finished in this manner, if the work is well done, possesses many advantages over the ordinary wood-covered structure. It is much warmer, being almost air-tight so far as the walls are concerned. It is safer, as fire will not eat its way through work of that kind for a long time. It is cleaner, as it will not prove such a harbour for insects. It may be made as handsome as desired, for, before the rough-cast is dashed, it may be laid off in panels of any shape by having strips or battens tacked over the soft mortar, which may be removed after the rough-casting is done and the coloring finished. It is much superior to the so-called brick veneered house, as it is much warmer, more exempt from fire and cheaper.

For 100 yards of rough-casting in the manner described the following quantities will be required:—1,800 lath, 12 bushels of lime, 1½ barrels best cowhair, 1¾ yards of sand, ¾ yard of prepared gravel and 16 pounds of hot cut lath nails, 1¼ inches long. The gravel should be sifted through a half-inch mesh screen, and should be washed before mixing with the lime putty.

To color 100 yards in any of the tints named herewith use the following quantities of ingredients:—For a blue-black mix 5 lbs. of lamp-black in the dash. For buff use 2 lbs. of green copperas, to which add 1 lb. of fresh cow manure, strain all and mix well with the dash. A fine terra-cotta is made by using 15 lbs. of metallic oxide mixed with 5 lbs. of green copperas. A dark green color is made by using 5 lbs. of green copperas and 4 lbs. of lamp-black. Many tints of these colors may be obtained by varying the quantities given. The colors obtained by these methods are permanent; they do not fade or change with time or atmospheric variations. Many other colors are used, but few stand like the ones named. A brick color may be obtained by the use of Venetian red and umber mixed in whisky first and then poured into the dash until the proper tint is obtained.

The following are the officers elect for the ensuing year of the Ontario Society of Artists:—Hon. President, Hon. G. W. Allan; President, M. Matthews; Vice-President, W. Revell; Secretary, Robert F. Gagen; Auditor, James Smith. Executive Council—C. M. Manly, W. D. Blatchly, Miss G. E. Spurr, W. E. Atkinson, A. C. Williamson, R. J. Hovenden, F. M. Bell-Smith. Industrial Exhibition Committee—T. M. Martin, F. M. Bell-Smith.

IN Germany the liability of employers for accidents to workmen rests chiefly on the law of insurance, which dates from 1884. All employers are obliged to insure their work-people and clerical staff, even when the employment is temporary and unpaid. There are special associations for different industries, and the statutes must be approved by the Imperial Insurance Office. Injuries include those which are internal as well as external, loss of intellect, memory or nerve. When compensation is claimed, it is necessary to trace the injury to some specific cause, and not to the mere normal exercise of the occupation. Generally the person who is to gain or lose most by the undertaking is held to be the employer. Thus, in building contracts, it is not the capitalist who advances the funds, but the master builders, carpenters, &c., who are responsible. Employers' contributions to the associations are proportionate to their annual expenditure in wages. The amount of compensation is based on the wages received by the workman during a year. So long as he is completely incapacitated, he is to be allowed two-thirds of his wages. For partial disablement he obtains a fraction of that maximum proportionate to the extent of the injury. In case of death, twenty days' payment (in no case less than 30 marks) are to be granted towards funeral expenses. The widow, until her remarriage, is allowed about 20 per cent. of her husband's wages, while 15 per cent. is allowed for every child under fifteen who has lost one parent, and 20 per cent. if it has lost both. The total compensation to widow and children must not exceed 60 per cent. of the deceased's wages. In case of remarriage she receives as composition three times the amount of her annual allowance. If the deceased was the sole support of parents or grand-parents, they may receive 20 per cent. of his wages during their lifetime.

SHAVINGS.

The City Council of Toronto has resolved that in future none but Canadians shall be given employment in the city service.

John W. Long, a prominent contractor, residing near St. Catharines, Ont., committed suicide by shooting himself on the 29th of April. Ill-health and loss of money on several large contracts in Buffalo and Tonawanda, are assigned as the cause.

The contract has been let for the erection of an opera house at St. Thomas, Ont., to cost $20,000. The building will be three stories, built of red pressed brick, and will have a seating capacity of 1,200, and a gallery, with a stage 32 x 50 feet, and four boxes.

Wm. Herod, a tuck pointer employed on the new drill shed at Toronto, was killed by falling from a scaffold on April 23rd. The coroner's jury found a verdict of accidental death, adding a rider to the effect that a by-law should be enacted compelling better safeguards to be placed on scaffolds.

Mr. Coatsworth gives notice in the Dominion Parliament of a resolution:—"That it is expedient to insert in every contract for any public work made hereafter a clause requiring the contractor to pay the workmen engaged upon such work a rate of wages at least equal to the current rate of wages paid in the locality where such work is being done, at and during the time such contract is being done."

THE members of the American Society of Civil Engineers who are meeting in annual convention at Niagara Falls, will visit Toronto on the 25th inst. by invitation of Sir Casimir Gzowski, ex-President of the Canadian Society. The members of the latter Society resident in Toronto, have arranged to give the visitors a fitting reception.

THE Court of Common Pleas at New York has decided that a plumber who is not registered in accordance with the provisions of the plumbing ordinance of that city cannot legally enforce the payment of his accounts. This decision is said to have fallen like a bomb in the ranks of about five hundred unregistered plumbers in that city, and the Health Department is crowded with applicants for licenses.

IN our correspondence columns will be found an interesting article, accompanied by illustrations, relating to the recent landslide at St. Albans, Que., by Mr. Chas. Baillairgé, of Quebec. It is a matter of some surprise to us that Mr. Baillairgé, or some person of like practical experience, was not chosen by the government to report upon the causes, etc., of this catastrophe. It will be remembered that in the case of the great landslide at Quebec, in 1889, where fifty persons were killed, Mr. Baillairgé's version of the cause of the accident prevailed over that of Prof. Laflamme, (who has been deputed to report on the latter occurrence) both before the Society of Civil Engineers and before the Supreme and Lower Courts, where the case was discussed.

THE effort of a company to secure the passage of a Bill through the Dominion Parliament giving them the right to construct an elevated railway through certain of the principal streets of Montreal, was nullified by the determined opposition of the citizens. The Bill, as it passed the House, provides that before construction shall begin, compensation shall be made to the owners of property which would be damaged in value by the carrying out of the enterprise. This provision of the Bill will it is believed be sufficient to stop the further progress of the scheme. In a city of compact area like Montreal, there does not appear to exist the slightest necessity for an elevated street railroad. The electric street cars answer all the requirements, and in placing property owners beyond the reach of possible blackmail, Parliament has done an act of simple justice. There has been too much juggling with public franchises of late in the city of Montreal.

ON the 13th inst., in the Chancery Division Court, before Justices Boyd and Meredith, the appeal of Mr. Neelon, contractor for the new Toronto city buildings, from the decision of Mr. Justice Rose, which affirmed that the architect had authority under the contract to dismiss the contractor, came up for argument. The court agreed with the construction put upon the contract by the trial judge, and dismissed the appeal with costs, unless the plaintiff chooses to pay the costs of such part of the proceedings as will be abortive in the event of a new trial, in case of which election and payment there will be a new trial. Mr. Neelon is said to have stated his intention previous to this appeal of carrying the case to the highest court of appeal should an unfavorable decision be recorded by the lower courts. Whether or not he still adheres to this determination we are not informed, but it is at least probable that the case will not terminate at the present stage.

WE regret to observe the published statement that dissension has arisen in the Hamilton Arts and Crafts Association regarding the disposition of the surplus of $110 from the late Exhibition. If, as is stated to be their intention, a section of the members resign and form a new society, the result is not likely to be satisfactory to either party. The history of the Arts and Crafts Association thus far would seem to show that when accorded the united support of all persons interested, one such organization might be made successful. On the other hand it is extremely probable that a division of effort would result in general failure. We therefore hope that in the best interests of the Arts and Crafts Association the members will be willing to endeavor to arrive at some adjustment of the present difficulty which will be satisfactory to all concerned.

THE Dominion Government will be asked to make a grant of money towards defraying the cost of a Dominion Exhibition in Toronto in 1895. The so-called Dominion Exhibitions which have been held in the past have not even in a moderate degree been representative of Canadian progress. An Exhibition which would be truly Dominion in character would be likely to result in adding to the population and business of the country. Something of the kind is needed at the present stage in our history, and we therefore hope the Federal and Provincial Governments will liberally assist the Toronto Board of Trade, the Industrial Exhibition Association and others interested in bringing the project to a successful issue.

A LARGE amount of stone is every year imported into Canada from the United States, displacing in the local market an equal quantity of native material. The owners of Canadian quarries do not appear to be sufficiently alive to the importance of making known and keeping before the attention of architects and builders the location, quantity, accessibility and price of Canadian building stones. We believe Canadian sandstones are available which, in color and quality, are equal to those imported from the United States. This being the case, it is not to our credit that foreign material should be so largely used. In view of the difficulty experienced in securing samples from Canadian quarry owners for the series of tests of Canadian building stones conducted a couple of years ago by the Ontario Association of Architects, the blame for the present condition of things would appear to be due in a considerable measure to carelessness on the part of owners of Canadian quarries. We regret to observe also a fondness on the part of some Canadian architects for the use of foreign materials, even in cases where an equally good Canadian article could be had. Architects who pass by native in favor of foreign material are quite as unpatriotic as the professedly Canadian company which gives work that should properly belong to Canadian architects into the hands of a foreigner. In this connection we observe that the affiliated building trades in New York City have passed a resolution that after June 1, 1894, they will "refuse to handle any imported decorative or other material, and will take any steps necessary to protect the industries affected." "The onus of this complaint," says Stone, "lies against the practice of wealthy men with snobbish tendencies favoring foreign material for their buildings, in other words awarding contracts to European firms for work that domestic firms could do as well and cheaply, thus enforcing idleness upon our workmen." We quite understand that in some instances it is necessary to go abroad for a suitable material, but this should not be done until the possibilities of home production have been exhausted.

THE MASSEY MUSIC HALL.

THE Massey Music Hall just completed in Toronto, was opened with a three days festival last week. The Music Hall, as announced in the festival prospectus, has been provided through the magnificent liberality of a wealthy citizen of Toronto, Mr. Hart A. Massey. It is also stated that in this building, Toronto possesses a music hall worthy of her position as the chief city and artistic center of this great Province. There is an old saying that "one should not look a gift horse in the mouth," but there are some circumstances connected with this enterprise which we desire to bring to the notice of our readers. It is quite noticeable that the official prospectus of the opening festival contains a number of portraits of persons who took part in the inaugural concerts as promoters and performers, but no illustration of the design of the building nor any mention of the architect's name.

The plans were imported from an American architect. If our architects were as well protected in their work as Mr. Massey has been in the business by which he has been able to accumulate his wealth, this would probably have been otherwise. Mr. Massey did a very generous and public spirited act in donating so large an amount of money $150,000 for such a purpose, but it was a very unpatriotic act, when he allowed any other than a Canadian architect to furnish the design.

We take exception to the claim that the building is a creditable and satisfactory fulfilment of the opportunity which existed when Mr. Massey came forward with his offer. We cannot go into an extended architectural criticism of the building, but wish to mention a few important particulars in which we consider it to be deficient. This we do without any reflection upon the architect. We do not know what limitations he may have worked under. The indications are that the principal aim was to get the largest possible number of sittings with the ground space and money available. The exterior is about as aesthetical as the average grain elevator. There has been no attempt to make the structure fireproof. The floors, platforms, stairs, and seats are all wood work of the most inflammable kind. The exits will never be comfortable even for ordinary use, to say nothing of emergencies. The arrangement of seats is good. Commendable taste has been shown in the window glass, which is very plain, of light cathedral tints, with a few portraits in stained glass. On the whole, however, the interior effect is bad, made so by the pretense to ornamental construction of the upper portion in the Moorish style of architecture. This style of work, more than almost any other, requires a very elaborate treatment for agreeable results. It would be hard to find an interior so devoid of pleasing lines as the one referred to. The color decorations are what may best be described by the word "tawdry." The whole scheme has been carried out on an ill-advised basis. A lot should have been provided in some part of the city where the surroundings would have been favorable, and large enough for a building to contain from one to two thousand more seats, with ample room for approaches, both on foot and by carriage, inside of the street line. This with an appropriate design would have given the city a monumental building, which would have produced an effect impossible to be attained in the location chosen, even if the lot itself were of sufficient size. A building of this kind should fill a double purpose. While providing for those who could pay the prices of admission a suitable place for the enjoyment of good music with all its elevating influences, it should be constantly exerting a no less positive influence for good, from the artistic standpoint, on all who come within sight of its exterior. Many more persons would receive the benefit of the latter than could afford the privileges of the former, and as an educator of public taste it would be at least as valuable through its architecture as in its utility for large audiences.

We think Canadian architects are in a measure responsible for the great mistake that has been made in this scheme. When the preliminaries were under consideration, the Ontario Association of Architects should have pointed out to the committee associated with Mr. Massey that the funds were inadequate for the purpose. This suggestion if unheeded should have been followed by a formal protest in unmistakeable language, placing the architects on record as opposed to such a work being undertaken under conditions which were certain to result in an obstacle to the development of architecture. This building will for a number of years prevent Toronto from having a temple of music of a character to meet the requirements. Such a position on the part of the architects we believe would have commanded respect from the public. Similar conditions not infrequently occur in regard to public buildings and we trust that the architects will in all such cases hold up a finger of warning as has been done elsewhere in some instances. We very much regret that the Massey Music Hall is not a worthy subject for one or two illustrations in this journal.

THE Journeymen Stonecutters of North America will hold their convention in Toronto the first Monday in August.

Messrs. Oakley & Holmes, contractors, have removed their office and works from 68 to 89 Wellington St. W., Toronto.

THE ONTARIO ARCHITECTS' ACT.

THE Ontario Association of Architects are coming forward again with an effort to make the Ontario Architects' Act effective. The subjoined manifesto issued to candidates nominated for election in Ontario states the reasons why the Act should be amended, and it certainly seems as if it would be for the good of all that it should be so amended. The Association ask for no special privileges or powers for members of the Association as opposed to the public, but have accepted fairly the essential character of the Act as a measure passed in the interest of the public. Nor is there any injury offered to any class of practitioners engaged in building at present. Wherever there are persons now practising as designers for others and to whom the title architect is an object, the need is regarded as right and it is proposed to throw open to them the Association on its new basis. Builders who design for themselves will be in exactly the same position as they are now; nor is it proposed to place any restriction upon their building for others without the intervention of an architect. In the city as well as the country there is much building that any experienced builder can do. But when it comes to the application of science or to artistic judgment and an architect is employed, the public—builders themselves—want to be assured that the name indicates certain qualifications. If the amendment can be established there seems to be no doubt that the profession of architecture will be raised and the whole building business with it. The following is the circular letter to the candidates for election:

OFFICE OF THE REGISTRAR,
CANADA LIFE BUILDING,
TORONTO, June 12th, 1894.

DEAR SIR:

The Ontario Association of Architects, incorporated in 1890, was founded, as the preamble to the Act of Incorporation states, for the better protection of the public interests in the erection of public and private buildings in the Province of Ontario, and to enable persons requiring professional aid in architecture to distinguish between qualified and unqualified architects and to ensure a standard of efficiency to the persons practising the profession of architecture in the Province, and for the furtherance and advancement of the art of architecture.

The act provides that membership of the Association can only be attained by passing qualifying examinations, and the distinction given to architects thus qualified is the title "Registered Architect."

It has been found in practice that the Act fails to secure the ends set forth in this preamble, because the title "Registered Architect" is considered to be of no practical advantage so long as there is no restriction as to the use of the traditional title Architect. For this reason the influence of the Association upon both students and architects is materially weakened.

The course of study required for the examinations of the Association has been of great service to such students as have come up for the examinations, but these students are the few. The majority decline to prepare for the examinations and many give openly as their reason that they can see no use in doing so when they can call themselves Architects without examination.

Many Architects also, who, as persons practising architecture at the time the Act came in force, were registered as members of the Association, have since withdrawn their names and support from the Association on the ground that they do not find it necessary to belong to it.

In this way there will soon be a majority of persons practising architecture in the Province who will not be members of the Association.

Building operations are, in the meantime continually growing more complicated and involving more branches of scientific knowledge. The education of an architect no longer consists only of an acquaintance with the ancient forms of design, but spreads, of necessity, over a wide field of scientific knowledge; and the difference between the trained and the untrained architect is now not in point of taste only, but in matters directly affecting the public safety.

For this reason it seems proper that the profession of architecture should be put upon the same footing as that of law, medicine, or surveying, since its proper conduct as regards the convenience, health and safety of the public is as much dependent as these professions upon the exact knowledge and skill of the practitioner.

Nor can it be said that a fundamental training that will raise the general quality of design in the Province, is an unimportant public consideration; for the Province is being built up, in most parts permanently, and may with the same material and the same cost be made either attractive or unattractive, according to the skill of the architects. But in a new country where there are no traditions of good design and no ancient standards of excellence constantly before us, the attainments of architects in this direction will depend upon the opportunity they may have for a training which shall enable them to go beyond what their surroundings can teach them.

The first step to ensuring in architects of the Province a standard of efficiency in the many branches of knowledge now necessary to an architect, is to make the right to use the traditional title "Architect" dependent upon the attainment of this standard, tested in the only possible way by examination. The Ontario Association of Architects therefore intend to petition at the next sessions of the Legislature, that the right to the title, "Architect" be restricted to such persons as have succeeded in passing the examinations of the Association, conducted on such a basis and by such persons as the government may see fit.

It is not, of course, proposed to restrict the right of designing or building to architects. It is only proposed that persons who design or build without being qualified according to the accepted standard be known by some other name than architects.

Nor is it desired to injure those who, at present, make use of the title "Architect." The necessity of admitting all such persons will prevent any immediate change in the condition of practice in the Province; but the process of education will be going on amongst students, and the good effect of the Act will appear after a few years in the general improvement of buildings in point of economy, safe construction, and sound sanitation; and also, there can be no doubt, as works of art.

I have been instructed by the Council to state the matter to you, and to ask you if you will give it your support in the House.

I am yours truly,

W. A. LANGTON,
Registrar Ontario Association of Architects.

ILLUSTRATIONS.

RESIDENCE OF MR. GEO. I. TUCKETT, HAMILTON, ONT. JAMES BALFOUR, A.R.C.A., ARCHITECT.

This house is built of Credit Valley stone and Beamsville pressed brick. The inside is finished with native and imported hardwoods of various kinds, except drawing room, which is finished in white enamel, and the attic and kitchen apartments, which are finished with pine in natural finish. The house is heated with hot water and lighted by electricity.

CANADIAN ARCHITECT AND BUILDER COMPETITION FOR A DRUG STORE.—DESIGN SUBMITTED BY "TOLEDO" AWARDED SECOND POSITION.

The author in submitting this design states that he has done his best to comply with the published conditions of the competition. He has endeavored to provide a convenient plan, and in designing the elevation has chosen a style adapted from the Spanish Renaissance. The material is Ohio buff stone and buff brick. The roof would be constructed of Spanish tiles. The woodwork would be painted in two shades of cream and white. The facade on the side street would be treated in a similar manner, the brickwork starting from the first stone course above the ground; the bottom 16 courses to be glazed bricks.

SUBURBAN RESIDENCE DESIGNED BY J. C. A. HERIOT, MONTREAL.

COTTAGE AT VALOIS A. F. DUNLOP, ARCHITECT, MONTREAL.

On old work the painter often wants to use a putty that dries quick, sandpapers easily, and sticks where it is placed. To make just such putty, mix dry white lead in a good grade of brown japan, add enough lampblack to color it a good bit, give a binding quality by putting in a few drops of rubbing varnish, and lastly give the whole a dash or two of turpentine. The more rubbing varnish is added, the tougher the putty and the slower it sandpapers.

The term "bay window" is applied to a projecting window rising from the ground on a polygonal plan: it may be half a square or half a sexagon (the latter being the most common) both of them have three sides. Sometimes they are built on plan as half an octagon—that is showing four sides. Those with more sides than four are not frequently used, and the two-sided or canted bay is the least common of all bay windows. When a projecting window rising from the ground shows a half circle, or a segment of a circle, it is called a "bow window," in reference to its shape. An "oriel window" does not rise from the ground like a bay window. It projects from the outer face of the wall, and is supported on a bracket or corbel. The word "oriel" formerly meant a small chamber or apartment. These distinctions of bay, bow, and oriel windows are often used synonymously; but the above definitions will be found to be the correct ones.

THE QUEBEC ASSOCIATION OF ARCHITECTS.

WE desire to call the attention of architects and students of architecture to the removal of the above Association from the Canada Life Building to the more commodious, handsome, and convenient rooms on the lower floor of the New York Life Building, Montreal. The former location was found to be too inconvenient for the easy access which is desirable, especially at night.

To reach the new rooms no climbing of stairs is needed. Under the new arrangement, the new rooms will be kept open on all days of the week, from 8.30 a.m. until 6 p.m., and on Wednesdays the hours will be extended until 9 p.m.

Those who visit the new rooms will be highly pleased with the success of the Association. All kinds of literature, books, etc., will be found there, for a thorough study and reference on all subjects dealing with architecture and building.

The Council are desirous that all architects and students should take advantage of the privileges offered by the Association. We have confidence that such opportunities will be valued and used as they deserve to be.

THE EFFECT OF FROST ON GREEN MASONRY.

DURING the construction of the new theater in Zurich, Switzerland, it became necessary to carry on part of the masonry during the winter. The contractors obtained advice from several sources as to the manner in which the work should be done, but as the recommendations were very diverse the Austrian Society of Engineers and Architects, which has made a special study of cements, limes, and mortars, was asked to recommend a course of procedure. The matter was turned over to the Cement Committee, and this body instituted a series of experiments, which are described in the following free translation from the report in the Society's journal.

The experiments were made in two ways, the first with brick masonry and the second with rubble masonry, using stone of two kinds. This appeared desirable in order to determine if there was any difference between materials which were unlike hydroscopically. The materials used were dry and free from snow and ice, and the mortar was mixed as stiff as possible. The limes and cements were all tested in the municipal experimental station according to the system of the Society.

The separate pieces of brick wall tested were about 3.28 feet long, 6.56 feet high, and 12 inches thick, and were made with lime, Roman cement, Portland cement, mixed lime and Portland cement, and slag cement. The test walls made with these five mortars were laid with unwarmed water from the city mains and with water warmed to a temperature of 77° Fahr. A series of tests were also made with Roman and Portland cements and cold water to which 7 per cent. of its weight of cooking salt had been added. All mortars were made with 1 part of the cementing material and 2 parts of sand. In the mixed mortars twice as much lime as Portland cement was used. The lower half of the walls was partly protected by timbers, but the upper portion was entirely exposed. A few tests were also made with brick masonry laid with Hausleitner's frostproof Roman and Portland cements.

The test blocks of rubble masonry were 3.28 feet long, 6.56 feet high, and 16 inches thick. The stone used was partly limestone and partly sandstone. These blocks were made with lime mortar, Roman cement mortar, and Portland cement mortar, mixed with cold and hot water and cold brine as before.

The brick walls were started the last part of December, when the temperature was 26° Fahr., and the 14 pieces were finished in about three weeks. The temperature of the air was taken three times daily until the middle of April, the lowest temperature being on January 2, when 3 degrees above zero Fahrenheit was registered. The walls were pulled down June 6. It was at once apparent that those pieces of masonry laid with mortar containing lime had suffered more from the frost in the exposed upper part than in the portions protected by timbering, since in the former the mortar had plainly been frozen. The following remarks give an idea of the condition of the walls, as revealed by an examination of the joints with a sharp iron.

1. Lime mortar mixed with cold water. The mortar in the joints had hardened but feebly, and the bricks could be pulled apart by hand without exercising any noticeable amount of strength.

2. Lime mortar mixed with warm water. The mortar in the joints had hardened feebly, and there was no adhesion between the bricks and mortar.

3. Roman cement mortar mixed with cold water. The mortar in the outer and inner joints had hardened moderately, and there was considerable adhesion between the bricks and the mortar.

4. Roman cement mortar mixed with warm water. The joints were quite brittle and the inner portions of the mortar not particularly well hardened; the adhesion between the bricks and mortar was quite good. The part of the walls protected by timbers was in better condition and excelled any of the preceding walls.

5. Portland cement mortar with cold water. The joints were hard and the mortar clung well to the bricks. The protected part was better than the other in this case.

6. Portland cement mortar with warm water. The joints were hard, the mortar adhered well, and the entire piece of wall was a little better than any of the preceding.

7. Lime and Portland cement mortar mixed with cold water. The mortar was badly mixed, brittle and crumbling, but adhesive.

8. Lime and Portland cement mortar mixed with warm water. The mixture was uniform in this case, but the mortar was brittle and not well hardened in the interior, although adhesive.

9. "Frostproof" Roman cement mortar mixed with cold water. The mortar was well hardened and there was a good adhesion between it and the bricks. A plaster of the same material put on a part of the wall at the request of Herr Hausleitner was thoroughly hard and without sign of injury.

10. "Frostproof" Roman cement mortar mixed with cold water. This mortar was well hardened and adhered very well to the bricks. A plaster of the same material was thoroughly hard and without defects.

11. Wittkowitz slag cement mortar with cold water. The joints were brittle and the mortar fell into little particles when scratched out with the iron. The inner parts which had hardened somewhat were crumbling and showed but a slight adhesion to the bricks.

12. Wittkowitz slag cement mortar with warm water. The condition of this wall was but slightly better than of the last noted.

13. Roman cement mortar mixed with cold water to which 7 per cent. of salt had been added. The mortar was brittle and crumbling, adhering but slightly to the bricks.

14. Portland cement mortar mixed with cold water to which 7 per cent. of its weight of salt had been added. The mortar was well hardened throughout and adhered well to the bricks.

The masses of rubble masonry were built on a succeeding year, being started on December 28 and completed about two weeks later, the temperature ranging from 7° to 25° Fahr.. The blocks were examined on April 7, and were found to be in the following condition:

Limestone Rubble. 1. Lime mortar mixed with cold water. The mortar was completely frozen and brittle, without any adhesion to the stones. The block had fallen completely.

2. Lime mortar with warm water. The mortar was entirely frozen, brittle and without adhesion.

3. Roman cement mortar with cold water. The mortar had hardened pretty well, but had not the slightest adhesion to the stones, which could be removed from their beds without injuring the latter.

4. Roman cement mortar with warm water. The mortar was quite well hardened, but did not adhere in the slightest degree to the stones.

5. Roman cement mortar mixed with cold water and salt. In this block there was a partial adhesion between the stone and cement, and the latter had hardened somewhat better.

6. Portland cement mortar with cold water. The mortar had hardened very well and the adhesion between stones and mortar was quite good.

7. Portland cement mortar with warm water. The conditions were the same as with the last block, although the adhesion may have been a trifle greater.

8. Portland cement mortar mixed with cold water and salt. The mortar was very hard and adhered to the stones very well. The tearing down of the wall required considerable strength and necessitated the use of bars and other tools.

Sandstone Rubble. 1. Lime mortar with cold water. The mortar was entirely frozen, brittle, easily broken, and without a trace of adhesion to the stones.

2. Lime mortar with warm water. The condition of this block was the same as that of the first.

3. Roman cement mortar with cold water. The joints were badly frozen, the mortar crumbling and slightly hardened. There was no regular adhesion between it and the stones.

4. Roman cement mortar mixed with warm water. This block was in the same condition as the last.

5. Roman cement mixed with cold water to which salt had been added. The mortar was well hardened and adhered fairly to the stones.

6. Portland cement mortar with cold water. The mortar was well hardened, but its adhesion to the stones was only partly good.

7. Portland cement mortar with warm water. The conditions were much the same as in the last block.

8. Portland cement mortar mixed with cold water to which salt had been added. The mortar had hardened very well and adhered firmly to the stones. The block could not be broken apart without tools.

The conclusions of the committee from these experiments are that in brick masonry laid in frosty weather mortars into which any part of lime enters should not be used. Roman cement mortars behave fairly well under such conditions, and Portland cement mortars give good results. The use of warm water gave somewhat better results, and salt materially increased the resistance to frost. With rubble masonry, using either sandstone or limestone, lime mortar was entirely out of place and Roman cement mortar gave poor results unless mixed with salt. Portland cement mortar behaved well, especially with the addition of salt. The final recommendation of the committee is that in laying brick or rubble masonry in winter to use only Portland cement mortar, mixed with salt if possible.

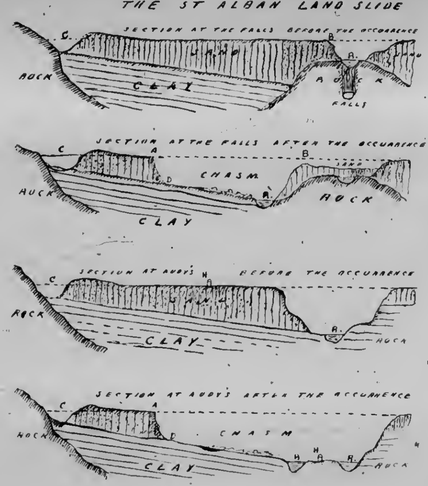
THE LANDSLIDE AT ST. ALBAN'S, QUE.

QUEBEC, June 3, 1894.

Editor CANADIAN ARCHITECT AND BUILDER.

SIR,—I have as requested by you put a few notes together anent the late slide at St. Alban's, on the North side of the river St Ann, some 36 miles from Quebec, or about 20 miles from where the river empties itself into the St. Lawrence. The accompanying plan or diagram of the locality and the several sections are self-explanatory, and almost sufficient of themselves to account for the occurrence, but I may add that as shown by the first or uppermost of the four sections, the river above the Gorge Mills, or eastwards thereof, ran at a level of nearly 100 feet above that pursued by its course westward, or, towards the St. Lawrence, there being a fall of some 95 feet over a ledge of rock separating the two.

Section 2 shows the channel over the falls, or leading to them, to be now obstructed by an immense amount of sand, clay and forest debris; the hog's-back of sand at B having precipitated itself into and filled the gorge at R, through which the river ran. This caused the waters to rise above the falls, or eastward thereof, to a height estimated by Professor Laflamme of the Laval University (whom the Local Government sent there to survey and report upon the accident) to 100 feet above their normal level. The hydrostatic pressure due to this head of water soon burst through the comparatively narrow barrier of sand—some 300 to 400 feet in width at this point—between the upper and lower levels of the river at the falls; when the impounded water made a new channel for itself at R, in section 2, and the rushing torrent reaching to a height of fully 50 feet above its normal surface—as evidenced by the St. Alban bridge, which though at that height above the stream, was carried away by the water—undermined the sandy shores above the clay formation, thus causing a large portion of the land to slide into the river and be swept away into the St. Lawrence, which it rendered thoroughly muddy, and ever thick with mud as far down as Quebec, discoloring the St. Lawrence for miles below.



This will not be wondered at when I say that the chasm created by the slide is, at the western extremity, not less than a square mile in area, and as its average depth is some 75 feet, or say 30 feet at A and 120 feet at the river, the quantity of soil and of sand and clay removed and carried away by the river cannot have been less than 75 million cubic yards at the western extremity of the slide alone, and much more than this if the portion be added from above the falls, which is said to extend some 3 miles eastward thereof, but which I did not make an inspection of.

The sections, though of course curtailed in length, of which the scale is some 20 times less than that of the respective heights or depths of soil, show how the material removed must have slid upon its clayey bed, well lubricated, so to say, by the percolating water through the sand, and of which at the time of my visit I counted not less than 80 streamlets issuing at D or from between the clay and sand in say 800 feet along the rear line A of slide, or where the land parted.

Some three houses were displaced or moved down with land towards the river, one of which, occupied by the Gauthier family, must be buried deep under the clay and sand; while those of Audy and Darveau, which before the slide were at H in section 3, were found the next morning to be at H in section 4, or some 25 arpents, says Mr. Laflamme, from where they started; and, due to one portion of the land sliding or travelling quicker than the other, had actually veered around by almost 180 degrees, though maintaining their verticality. The translation having occurred at dark and accompanied by roaring and fearful noises all around them, due to the rush of waters, it was only at daylight the next morning that Audy and Darveau found that they had travelled nearly a mile from their former position on the hill.

The disaster at St. Ann, some 20 miles further down the river, was entirely due to the rush of waters from the St. Alban blockade, after they burst the boundaries, as they then rose so high, as already stated—some 10 feet or more at St. Ann, where the river is so much broader than at St. Alban—that they gradually ate away the shore for a distance of some 1700 feet north eastward of the C. P. R. bridge, several houses and outbuildings being thereby undergrounded and tumbling into the river, while about a dozen others were at the time of my visit being hastily moved back to prevent the possibility of further damage.

While the accident at St. Alban could not have been foreseen or, if so, guarded against, the same thing cannot be said of St. Ann, where every time there is a freshet, the shore is eaten into and made to recede towards the east or village.

A man named Gorlin, who was busy putting his house back, informed me that this was his second removal in 8 years, due to a like cause. At St. Paul's Bay, where I was called lately to advise them as to their proposed aqueduct, I found the same features exactly as at St. Ann's, though on a smaller scale, the Riviere du Gouffre being of less capacity than the other. The citizens there, however, had faced the difficulty and set to carrying out the self-suggestive mode of protecting the sandy river shores by piling driven to some 10 feet below the bed of the river or to a hard bottom; some 500 feet lin. of this work had been done at a cost of only $300.

The same remedy is required at St. Ann, or the balance of that portion of the village north of the railway will go with the next freshet. It is passing strange that this idea of piling their respective frontages should not have occurred to these riparians, who cannot surely have forgotten already how, only a few years ago so to say, they were witness to the way in which piles were driven to stand the piers of the bridge on a sure foundation. This piling of some 1700 of the river frontage here might cost, say $5,000, at the utmost, while as appears by the figures given by a Quebec journal, the "L'Electeur," the loss in ruined tenements and removing others is not less than $20,000.

As a minor feature of the accidental outcrops at the lines of parting of the removed material, the student in geology may see both at St. Ann and St. Alban, as could also be seen at Portneuf when the hill was excavated into for the bridge abutments, layer upon layer of clay in the process of formation into stratified beds of stone; and I may say here, that in visiting a sand quarry at Beauport while surveying the locality for the then proposed and now constructed aqueduct to the lunatic asylum, it was my good fortune to see, which I never had a chance at before, perfectly defined, horizontal layers of sand of equal thickness, some 6 inches or thereabout, apparently in the process, a lengthy one though it be, of elaboration into stone.

Again adverting to St. Alban, it is to be feared that in the not remote future there may be a recurrence of these slides in adjoining parishes under concomitant circumstances; the subsoil being very probably honeycombed by water infiltrating through the overlying sand, and the underground rumblings often heard in these vicinities seem to give warning of the impending danger.

Only three years ago a slide, though on a smaller scale, occurred a little above the St. Alban on the same river. Some 20 years ago or less, an exactly similar slide of a mass of sand and loam over its well lubricated bottom of hard clay, took place at St. Valier, when an extent of land some several acres in area moved bodily, trees and all left standing, into river Boyer, causing it to change its course entirely at that locality; while others on all scales, large and small, are of daily occurrence in some part of the world or other.

C. BAILLARGE.

ON THE ADAPTATION OF A PRICE BOOK TO MEET VARYING RATES OF WAGES.

(FROM "LAXTON'S PRICE BOOK.")

THE following table shows a method by which an approximate estimate of the proportion which labour bears to material in each of the several branches of the trades, may be calculated:

Trade	Approximate proportion for Material.	Approximate proportion of Labour.	Proportion of total requiring adjustment.
Excavators, navvies or other labouring work			The whole, except such margin as may be apportioned to cartage.
Drainage work	66⅔ per cent.	33⅓ per cent.	one-third.
Bricklayer	66⅔ " "	33⅓ " "	one-third.
Mason	33⅓ " "	66⅔ " "	two-thirds.
Carpenter	66⅔ " "	33⅓ " "	one-third.
Joiner	33⅓ " "	66⅔ " "	two-thirds.
Plasterer	50 " "	50 " "	one-half.
Plumber	75 " "	25 " "	one-fourth.
Painter	40 " "	60 " "	three-fifths.

MEMO.—Each of the above carries with it its own labourers in attendance. The trades of slater, smith and founder, gas fitter, bell-hanger, etc., are purposely omitted, as they are mostly dealt with upon a different basis, and in fact should be regulated by their prime cost.

Example.—Supposing it be desired to adjust an estimate or measured account upon the basis of mechanics' wages at 10d. per hour, instead of 9½d., then add one-nineteenth (or say 5¼ per cent.) on to the proportion of such trades as is given in the outer right-hand column thus: If the joiner's bill in the summary of an estimate, amounted to £450, the proportion attributed to labour would be two-thirds, or £300, to which we add the one-nineteenth, for increase in wages, making £15 15s. 0d., and raising the total to £465 15s. 0d.

Or supposing the case of the plasterer's bill amounting to £90, the proportion attributed to labor would be ½, or £45, to which we add one-nineteenth, or £2 7s. 4d., raising the total to £92 7s. 4d., as the corrected amount to meet the altered rates of wages.

Or, again, suppose it be desired to apply London prices to suit the lower rate of wages of a provincial town, say 8d. per hour, hour instead of 9d., then deduct from the proportion one-ninth (or, say 11 per cent.), thus: If the bricklayer's bill amounted to £1,130, the proportion attributed to labor would be one-third, or £376 13s. 4d., from which deduct one-ninth, or £41 17s., giving the revised total as £1,088 3s. to adjust the variance in wages.

STUDENTS' DEPARTMENT.

INTERCOMMUNICATION COLUMN.

This column is intended to afford a means of correspondence for students, builders and all our readers desiring information they cannot otherwise obtain. Questions for which an immediate reply is required should be marked "Urgent." Names and addresses of correspondents must be sent with their communications, but these may be signed with initials or otherwise for publication.

QUESTIONS.

[20]. I am roofing a brick building, which we faced with pressed brick. The brick were only damp enough to lay nicely and the walls well protected from the weather. A white substance which seems to come out of the bricks themselves now covers the wall in many places, thus greatly disfiguring it. We had the same trouble on a building which we built over a year ago. I write hoping that you may be able to suggest a remedy. Do you think oiling the wall after cleaning it with acid would be a permanent cure. A. E. C., B. Columbia.

[21]. Counting 25 bricks to a cubic foot when laid, and allowing fifteen per cent for waste, how many bricks would it take to build a chimney of square cross section, having its outside dimensions 6×6 feet at the base and 3×3 feet at the top, its inside dimensions 2.5×2.5 feet at the base and two feet at the top? (The fifteen per cent. to be added to the theoretical number required to build the chimney.) The height of the chimney is to be 60 feet. With the same diameters, how many bricks would it take to build it 70 ft. high?—STUDENT.

REPLIES.

[19]. "County Builder."—To give a full answer to your question we should have to print a table giving the comparative strengths of ropes of all diameters, but a few examples may suffice you at present. For instance a 1 inch girth hemp (hawser) has a breaking weight of .20 tons, whereas an iron wire of same girth will only break at 1.40 tons, and a steel wire at 2.50 tons. A 2 inch hemp breaking weight .80 tons, iron wire 5.60 tons, and steel 10.00 tons.—[Ed. Inter. Col.]

[20]. So far as we can learn, there is no process which is effectual in preventing the exudation of magnesia from brick work. We are informed that there is a standing offer on the part of the leading brick manufacturing companies of Canada and the United States of $10,000, for the discovery of a process which will prevent efflorescence from brick work. If the bricks before being laid in the wall, are dipped in linseed oil to the depth of an inch and a half on the surface to be exposed, it will prevent to a considerable extent the magnesia from coming to the surface. The cost of dipping would be from sixty to seventy cents per thousand. Experience in Toronto and elsewhere has shown, that with constant washing by rain and drying by sun, the efflorescence usually disappears to a large extent, if not entirely, after the building has been exposed one or two seasons to the weather. This being the case, it is considered hardly necessary to go to the expense of dipping the bricks in oil. So far as our information goes, we do not think that oiling the wall after cleaning it with acid would prove a satisfactory remedy. We understand the amount of magnesia in the brick depends largely upon the depth at which the clay used in their manufacture is obtained. In bricks made from clay dug at a considerable depth below the surface the quantity of magnesia is less than in those made from surface clay. We might add that the defect to which you refer appears not to be confined to any particular deposit of clay, but it is incident to bricks everywhere. The problem of how to avoid it is one which has for a long time given brick manufacturers a good deal of anxiety. If any of our readers are possessed of any additional information on this subject, we will be pleased if they will contribute it.

[21]. In order to get the volume of brickwork in the chimney it is necessary to find the volume of the outside frustum of a pyramid and that of the inside frustum or flue, and to subtract the latter from the former. The volume of a pyramidal frustum having its base and top parallel is found by adding together the areas of its base and top, and the area of their mean proportional, and multiplying their sum by ⅓ the perpendicular height. The area of the base of the outer frustum is 36 square feet: that of the top 9 square feet; their mean proportional is $\sqrt{36\times9}$=144 equals 18 square feet. Then 36+18+9=63; 63×20=1260 as the number of cubic feet without deducting the volume of the flue. The flue has its base area 2.5×2.5=6.25 square feet; as its top area 2×2=4; the mean proportional between these two areas is $\sqrt{6.25\times4}$=25=5. Then 6.25+5+4=15.25; 15.25×20=305 as the number of cubic feet in the flue; this being taken from the outside volume 1260 leaves 955 as the number of cubic feet of brickwork. If there were 25 bricks to the cubic foot that would call for 955×25=23875 bricks without allowing for waste, and fifteen per cent. of this would be 3581 for waste; so that the total number required be 27476 bricks.

SALT WATER FOR BRUSHES.—The water in which brushes are kept during the warm summer months, often though it be changed, is apt to get foul. To prevent this put a little salt in the water.

A NOTABLE CASE OF MOVING A BUILDING.

A NOTABLE instance of removing a large building was the removal at Rouen, in France, of a large timber and iron shed, 194 ft. long, with a 97 ft. span, over a distance of several hundred feet. The structure was made up of twelve trusses, supported on double posts at each end, and the total load to be lifted amounted to about 180 tons. The crucial part of the undertaking was in the lifting of the twenty-four supporting posts at one and the same time, and it was indispensable also that this raising should be accomplished in a manner which would not in the least degree alter the relative positions of the posts. One circumstance largely favoring the undertaking was that the slope of the ground over which the shed had to be moved was slight, and that the posts, when in their new position, would require raising to the extent of only about 10 in. The mechanical appliances necessary, therefore, were comparatively simple, comprising only some winches, cables, and screw jacks, some strong blocks, and the special trucks which had to be built to carry the posts in transit. Rails and sleepers, necessary to complete the outfit, did not add greatly to the expense. The first operation consisted in laying a track underneath each line of posts, and then building around each post a truck on to which, subsequently, the posts were lifted. As soon as all the trucks had received their loads they were coupled together by iron rods so as to transmit the traction in the line of the posts, and also to preserve the proper distance between them. Somewhat beyond the far end of the distance to be traversed two piles were driven into the ground almost in line with two rows of posts, and at each side of these piles another and smaller one was driven to serve as the fixed points for the cables used in hauling. The latter, starting from these, passed successively around pulled blocks on the two heavier piles, then around blocks fixed to the leading trucks, and finally were wound on a winch placed inside the building. A graduated plank was laid down along the whole length of the route to aid in securing uniformity of progression in all the trucks, and the whole operation was carried out expeditiously and successfully.

So far as is known, wall paper was originally made by the Chinese in square pieces, about 20 inches wide and 20 inches long. It was probably pasted on the wall, and used in some such manner as the Spaniards used their stamping leather, taking the place of the arras of the French, and the tiles of the Dutch. China stands prominently out as being able to make more from paper and pulp than any other nation.

The object of shingling a house, or other building, is to keep out the rain; from the manner in which some carpenters do their work, says the Kansas City Architect and Builder, it would seem as if their object was solely to see how many shingles they could make one nail hold in place until they got off the roof. But the good and conscientious workman lays the shingles right side up, spaces them evenly, puts butts even, and drives two nails in each shingle over four inches wide.

A section through in a drawing will tell more about the arrangement of the internal details than dotted lines ordinarily can. Therefore, says an English architectural paper, after a sufficient number of side views and a plan have been made—or, better, an isometrical picture of the device illustrated—enough cuts should be made through different parts of it to clearly show the inside parts. This practice will generally obviate the necessity for a separate drawing of the full details on experimental work and on tools, where it will be found necessary to draw but few such details of the more complicated shapes. Dotted lines for every covered part are an abomination when made by the average draughtsman. Few men have the artistic skill thus to depict the transparent effects so that an intelligent view is given of the internal parts. A section here and there, on the other hand, makes all parts clear and so well within the capacity of the most ordinary draughtsman to depict, and in the power of the most crude mechanic to read, that there can be no two opinions as to the advisability of plenty of sections and few or no dotted lines. In a long experience we have found it to pay, as a corrective, to make sections, for many of the mistakes of draughtsmen may thus be caught and remedied.

A NATURAL bridge is said to have been discovered on the Columbia river near West Kootenay. It is composed of grey granite, allied to syenite. The piers on each side are 20 feet high, when the arch begins to spring and rise in the centre to a height of 90 feet above the ground. The distance from pier to pier is 264 feet, and this enormous span is covered by a roof of granite 30 feet wide, and varying in thickness from 10 feet at the sides to 12 feet in the centre. The form of the arch is that of a rainbow, the under side being smooth, but not water-worn, and without angles or bosses. It is cracked in radiating lines, which divides the centre into self-supporting keystones, but the joints are quite close, without fissure between them. The sides of the piers are as smooth as the arch, and great firs and cedars grow beneath the arch. This remarkable monolith does not appear to have been caused by the wearing away of the rocks around it, nor by falling from a higher level, but seems to have either been elevated en masse or left standing on the subsidence of the surrounding land.

MONTREAL.

(Correspondence of the CANADIAN ARCHITECT AND BUILDER.)

The Hon. Mr. Nantel, Minister of Public Works for this Province, has returned from a trip to Europe, Egypt and the Holy Land. He is reported to be much improved in health.

The Sanitary Engineer has reported to the Health Committee that certain large educational establishments now in process of construction have failed to carry out by-law No. 105, section 26, which requires them to submit to the Board of Health plans of the internal arrangements, plumbing, etc., after being duly notified to do so.

At a meeting of the Council of the Province of Quebec Association of Architects held in their new rooms in the New York Life Insurance Building on May 29th, Mr. Joseph Haynes tendered his resignation, which was accepted. Mr. A. C. Hutchison has consented to act as secretary till the next annual meeting. Mr. Hutchison is known to be a hard worker in the interests of the Association, and the secretaryship could not be in more capable hands.

The members of the Carpenters' and Joiners' Union are not likely to again order a strike in this city, at least until the recollection of their present defeat shall have become less painful. They demanded that their working hours be reduced to nine instead of ten, and that their wages be increased to a minimum of 20c. per hour instead of 16c. per hour. These demands, the master builders refused to grant. After having lost five weeks of their time, and an advance in wages, which they might have got from their employers at first, they have been compelled to return to work at the same hours as before, and some for less wages than they were getting previously. Indeed they have not all succeeded in getting employment. Some employers took non-union men on during the strike, and they now refuse to replace them by the strikers. Those union men to whom employment has been given are not recognized as such. The men claim that about fifty of the builders have acceded to their demands, but this statement appears to be exaggerated. It has only been possible for me to find two, and of these one has failed since the settlement, and the other I hear discharged his union men immediately after the settlement. The Carpenters' and Joiners' Union probably selected for their strike the slackest time we have had for the last twenty years. There are very few buildings in course of construction this year; and the foundations of these are hardly in yet. The only work that is always going on perhaps is jobbing, which in the month of May is a little more active than usual. All this no doubt helps to account for the little success which rewarded the carpenters' recent effort to force payment of a higher rate of wages. Speaking to a prominent contractor the other day in this connection, I was told that he had only fifty men in his employ at present; when business is brisk he employes from one hundred to one hundred and fifty men. Of the fifty at present employed, about half are union men to whom before the strike he offered an advance in wages of ten per cent., which was refused. He also said that a good many of his former employees applied to him for employment after the strike, but he refused to grant their request. The absurdity of this strike when the business is so dull is clearly illustrated by the fact that hundreds of men are necessarily idle, and as this contractor said: "Applicants are so numerous that I had to put up a notice at my office entrance to prevent them from coming in." Last week this contractor said that he received over 70 applications for employment, and at the beginning of this week about thirty. This is not the opinion and experience of one man only, but of the most prominent contractors of the city. A few architects interviewed on the subject with one exception said the strike affected them very little; one said it had been the means of stopping work on ten of his buildings; but it is yet early in the season, and with men plentiful, there is time enough in which to gain the lost time.

HAMILTON, ONT.

(Correspondence of the CANADIAN ARCHITECT AND BUILDER.)

The City Council have been petitioned to further extend the fire limits.

The City Council recently passed a by-law exempting builders from payment of water rates. It is said an effort will be made to have the by-law declared to be illegal on the ground that there was not a quorum of members of the Council present at the meeting.

An Arts and Crafts Exhibition in Canada is a sign of progress. Hamilton exhibition, which was held in the well-lighted rooms of the Art School, opened on Queen's birthday and closed on June 2nd. About 250 persons visited it daily, and most of them will undoubtedly have received an object lesson as to the real meaning of art and handicraft. The walls were covered with pictures by local artists, and 40 selected works from the Ontario Society's exhibit, interspersed with some excellent works loaned by Hamilton citizens. The "Crafts" section occupied the centre and filled a row of benches across the end of the large lecture room. The architectural designs were hung in the hall and staircase. Messrs. John Ireland, Stark Gordon, J. S. Gordon, A. Stuart and L. Stuart; Madames Ireland, Hull and Birely, and Misses Linton, Shed, Galbraith, L. Hamilton and Boine, were the most conspicuous exhibitors among local artists. Mr. S. John Ireland's "Attraction in Reflection" and "Washed Ashore," and Miss Galbraith's "My Mother's Garden," were worthy of the praise bestowed on them. Space is too limited to review the pictorial section, and as many of the best works have been lately considered while on exhibition at Toronto, it is unnecessary to do so; it is presumed also, that the readers of the CANADIAN ARCHITECT AND BUILDER will be more interested in the Architectural and Crafts' sections. The architectural exhibits consisted of design for exhibition building by E. Patterson; city hall in French Renaissance style,—the planning is good and the facades are effective. James Balfour, A.R.C.A., exhibited a perspective, in line, of a municipal building —a good composition and a most creditable bit of draughtsmanship; he had also a perspective of his Detroit Museum of Art. W. A. Edwards had a fairly good design for a school, but the coloring detracted somewhat from its merits. R. Cloheey had a pen and ink of additions to Loretto Convent; Messrs. Rastrick had a colored perspective of Mr. Lucas' house; John A. Sellard exhibited his silver medal drawings for a museum, art school and gallery; A. W. Peene had a nice bit of pen work, a porch shelter of very appropriate design. The wallpaper designs by A. McKenzie, Gilbert Clayton and Misses Lucy McInnes, D. Trigge, Lena Bowman, were good, as were also the tiles by Thos. Davidson. Designs for painted ceilings—by Frank Nairn, Misses L. Bowman and Marguerite Jackson. Design for grate and overmantel, by Miss Ida Thompson—this drawing was quite refreshing; to see such good technical work by a girl is unusual; this drawing was exhibited at Chicago. Brasswork—a lectern by Chadwick & Sons.

Wood carving and cabinet work was best represented in the Crafts' section. J. Hoodless & Son had a magnificent bedstead in Empire style, designed by Jas Barton, and carved by J. A. Thompson and W. Taylor; a bric-a-brac cabinet by Malcolm & Souter—designed by J. Souter, carved by Jas. Thompson, and cabinet work by R. Newbegging. This was sold for $110. There was also shown centre tables by R. Boase and Mrs. Robt. Evans; flower stand by Miss Ethel Hamilton; folding screen by Amy Barnard, this received an award at the Columbian Exhibition; carved panels, F. J. Morrison—particularly good examples of Renaissance; clock cases, etc., by J. Souter and J. Thompson. Needlework, designed and wrought by Madames W. H. Ballard, Leith, Wright, McBrier; lace, Mrs. A. W. Peene and Miss C. McIlroy, also original designs.

In bent iron work, Miss M. E. Anderson, of Glasgow, Scotland, had a varied display.

In carriage painting, Malloy and Malcolm had a case of samples showing every stage of carriage painting up to 14 coat work; this exhibit attracted everybody's attention.

In the German specimens of raised wool work, loaned by Senator Sandford, the horses' heads were really wonderful, being shaded and shorn till it was a work of modelling as well as needlework.

A modelled figure of Venus was exhibited as the work of Miss R. A. Baine, the indefatigable secretary of the Association. In silversmiths' work Andrew Dwine had a nicely modelled figure of a curler, and his brother Robert an automatic perfume fountain—these exhibits were loaned by the Merriden Brittania Co. In stained glass there were designs by Walter R. Dulf and Arthur Adam.

The exhibition was a success financially, $214.50 being received at the gates. Over $100 is to be expended in the purchase of works of art to form the nucleus of a collection for an art gallery.

THE MARITIME PROVINCES.

(Correspondence of the CANADIAN ARCHITECT AND BUILDER.)

The citizens of Moncton, N. B., are very much in earnest in their determination to secure harbor improvements for the town. With regard to the need of such a work and the valuable results to flow from it, its advocates are able to point out that Moncton has already made fine progress as a manufacturing town; that it is the natural outlet of varied and extensive natural products seeking foreign markets; that it is well located to become an important manufacturing centre, and that the town already has a good record as a shipping port. Coming now to the possibility of providing the town with a good harbor, the Harbor Improvement Company present an elaborate series of plans showing how, by an expenditure that would be very moderate compared with the cost of similar works at other ports, the place can be provided with a wet dock covering 14 acres, with also a dry dock for making light and another for more extensive repairs to vessels. The Petitcodiac river flows beside the town. Just beside the sugar refinery, cotton mill, B. & M. railway terminus and the pumping station, flows Hall's creek, a winding tidal stream, tributary to the Petitcodiac. The proposition is to convert this Hall's creek into a wet dock, with, as already stated, 14 acres of available water for ships. Wharves will be built along the banks of this dock to accommodate vessels as the business develops. The entrance would be through a lock with double gates, and out of which the water could be withdrawn, leaving a dry dock where a vessel could make light repairs. If more extensive repairs, involving considerable time, were needed, another dry dock at the extremity of the wet dock can be provided for. As the land is ordinary high marsh, there would be no difficulty in excavating wherever necessary, and the construction material could be of wood and practically indestructible, because experience has proved that timber in the Petitcodiac river is free from worms.

Hence it is claimed, the cost would be relatively small, considering the amount to be done and the value of the works when completed. The largest ships could be accommodated, for the largest vessels can ascend the Petitcodiac to Moncton. The wet dock would be steadily supplied with fresh water from the creek above, or by pipes from a reservoir within two miles of the town. When completed the new harbor would be beside the sugar refinery and cotton factory, with connection with the I. C. R. and B. & M. railways, and special facilities would be afforded for the establishment of new industries along the wharves, one of the inducements being a nominal or low rate water supply, and another easy access by water to the coal mines of Cumberland, Nova Scotia, and by rail with the quarries of Westmorland, Albert and Kent counties, to say nothing of the lumber and farm products of the surrounding country.

It is stated as a strong point in favor of the proposed work, that old shipping men not only recommend it but will back it with their support. The people of Moncton themselves are prepared to aid the project in a substantial way and the company are willing to thrust their hands deep into their own pockets, believing the investment would be a good one. The growth of Moncton, they point out, would be for the advantage of the traffic on the I. C. R. and of the trade of St. John, and for the good of the whole country. Therefore they maintain the whole country should favor the scheme.

A mass meeting was held in Moncton a short time ago and the sentiment as expressed was strongly in favor of the new docks. The Provincial as well as the Dominion government will, it is believed, support the scheme.

A move is being made by Campbellton merchants to improve their harbor. According to the survey of the river made in 1839, which appears to be the last general survey made, there is 23 feet of water in the channel opposite the ballast wharf at the lowest neap tide. But on the traverse there is at times only 11½ feet. This gradually deepens, however, till at the Battery point there is plenty of water for the largest ships. The plan proposed is to dredge out the south channel, which joins the north channel opposite Point La Garde. This would make a direct course up the middle of the river, and it is contended the current would keep it clear when once opened up. About two miles would require to be dredged, but the channel is partly open now. A petition was sent to Mr. McAllister, the representative at Ottawa, and it is believed there will be little difficulty in getting it through the House.

A. H. Mc.

PERSONAL.

The death is announced of Mr. Charles Goswell, a prominent builder and contractor of Winnipeg.

Mr. F. H. Herbert, architect, Toronto, has recently removed to new and more commodious offices at 32 Queen street East.

The Hon. William Harty, of Kingston, has been appointed Commissioner of Public Works for the Province of Ontario to fill the vacancy caused by the recent retirement of Hon. C. F. Fraser.

Mr. J. A. Ellis, architect, of Toronto Junction, in conjunction with Mr. Wm. Fingland, late of Toronto, has opened an office in the city of Baltimore, and is about to temporarily remove to that city. On the eve of his departure from Toronto Junction he was tendered a complimentary banquet by a number of the prominent citizens. Mr. Ellis' popularity is well deserved, and his departure is the subject of much regret.

The government are being urged to restore the duty on white granite ware to 35 per cent., as at the reduced duty of 30 per cent. difficulty is being experienced in organizing a company to continue the large industry at St. Johns, Quebec, formerly carried on by the St. Johns Stone Chinaware Co.

THE WUENSCH AND MELAN SYSTEMS OF FIRE-PROOF FLOOR CONSTRUCTION.

WITHIN the last few years Austrian engineers have been adopting various systems of combination iron and concrete arch floor construction in buildings where the floors are subjected to heavy loads, with a considerable reduction in cost and a great gain in the rapidity of construction over the old form of brick arch construction. For some years the Monier system, illustrated and described in Engineering News of May 23, 1891, and Feb. 16, 1893, has been most generally specified for floors, but recently two other systems, the Wuensch and Melan, have been very successfully used in a number of large buildings. The application of these two systems to actual structures is shown in the accompanying illustrations.

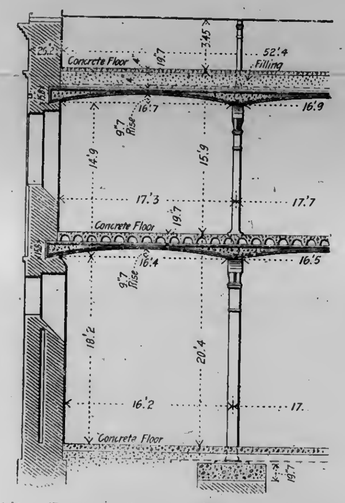


FIG. 1.—TRANVERSE SECTION OF BREWERY AT BUDAPEST, SHOWING WUENSCH SYSTEM OF IRON AND CONCRETE FLOOR CONSTRUCTION.

In Fig. 1 is shown the construction of the Wuensch system as used in the floors of a large brewery at Budapest, Hungary. In this building the second floor had to be designed for a load of 240 lbs. per sq. ft., and the third floor for a 80 lbs. per sq. ft. load. The space to be covered was 174 × 52½ ft. Two rows of columns were run lengthwise of the building 18 ft. apart and 16 ft. from the side walls of the building, and upon these was placed the system of concrete and iron arches shown in the illustration (Fig. 1). As will be seen, this system consists of a series of arches spanning the spaces between columns lengthwise of the building, and these arches carry other arches which span the space transversely. The longitudinal arches act simply as girders which support the arches forming the floor proper and are only 15¾ ins. wide, 14 ft. span and 1.4 feet rise. They are made up of four 2.16 × 2.16 × 0.28 in. angles, two of which are curved to form a bottom chord, so to speak, for tension, and two of which form a horizontal top chord for compression, and are filled in with concrete. It will be seen that the system is simply a modified form of the Monier system, in which the wire nettings are replaced by stiff angle or T-sections.

The tranverse arches are constructed in exactly the same manner as the longitudinal arches, except of course that they form continuous vaults the entire length of the building and use

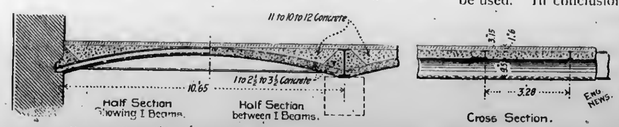

FIG. 2.—THE MELAN SYSTEM OF IRON AND CONCRETE FLOOR CONSTRUCTION.

T-sections instead of angles for the iron skeleton. Two of these arched vaults have spans of 16 ft. and one a span of 18 ft. and the iron frames are placed 7.9 in. apart for the second floor and 13 ins. apart for the third floor. The T-sections used are 1 × 1 × 0.15 in. The composition of concrete was 1 cement, 2½ sand and 3½ broken stone.

The time taken to construct this floor with 8,500 sq. ft. of area was four days; the centers were allowed to stand one week after the concrete had been placed. Mr. Schustler, the designer, works out the cost of the floor, as compared with a floor consisting of twelve 14-ft. span brick arches laid between I-beam girders supported on cast iron columns (a design which was at first proposed for the work) as follows:

	Brick.	Wuensch.	Saving by using Wuensch system
Weight of floor per sq. ft..	500 lbs.	320 lbs.	180 lbs.
Weight of cast iron columns	82 800 lbs.	65,000 lbs.	17,800 lbs.
Weight of wrought iron used	108,400 lbs.	56,400 lbs.	52,000 lbs
Volume of brick or concrete	13,603 cu. yds.	798 cu. yds.	502 cu. yds.
Depth of floor.....	40 ins.	6.7 ins.	33⅓ ins.

Mr. Schustler further states that the saving in cost over brick arches in this floor was 30%. It is to be remembered, however, that this statement applies to the cost of materials and labor in Hungary. The high price for labor in this country would make the saving considerably less.

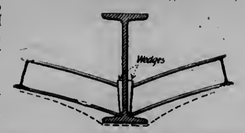

FIG. 3.—CONNECTION OF CURVED I-BEAMS WITH FLOOR GIRDERS, MELAN CONCRETE AND IRON FLOOR CONSTRUCTION.

The second system of floor construction shown is what is known as the Melan system of arch construction. As already described in Engineering News, this system consists in embedding curved I-beams in concrete and has proved very strong under heavy loads. The illustrations, Figs. 2 and 3, show the system as applied to the floor of the spinning-room of a large factory at Tetschen, in Austria. This floor has an area of about 40,000 sq. ft., and is loaded with heavy spinning machinery. As will be seen the concrete is filled in between the beams, coming down below the concave flange of the curved I-beam and being level with the upper flange of the arch. A poorer quality of concrete is generally used for the spandrels and ashes are used for filling. The connection of the curved I-beams at the floor girders is shown in Fig. 3, where it will be seen that simply a couple of wedges are used, there being no riveting of any sort.

The manner of laying the concrete is first to build a centering with tight lagging conforming to the intrados of the arch. The manner of constructing the centering is shown in the accompanying sketch, Fig. 5. The iron frames are then placed and the concrete rammed in place in layers, as is also shown in Fig 5. In this manner a gang of 14 men have laid from 700 to 800 sq. ft. of floor in a day of ten hours, including the spandrel filling of poorer concrete which, of course, had to be laid separately. This gang consisted of four men placing the I-beams, fastening them and placing the centering; one man for sand and one for cement; four men mixing the concrete; two men carrying the concrete and two ramming it into place. With

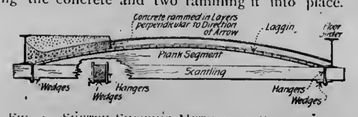

FIG. 4.—SKETCH SHOWING METHOD OF CONSTRUCTING MELAN CONCRETE AND IRON FLOORS.

this gang the amount of concrete laid per hour per man was 2 cu. ft. This record is low, however, and on bridgework the average amount of concrete laid is 5 cu. ft. per man per hour.

In Fig. 2 it will be seen that a tie-rod has been used in the arches abutting against the wall. Usually the stiffness of the I-beams is sufficient to prevent any movement without these. The arrangement of the I-beams and the depths of the concrete for different span arches are shown in the accompanying table:

Space, feet with rise of 1-2 to 1-15	Depth. ins.	I-Beams— Dis. apart. Weight. ins.	Weight, lbs. per sq. ft. of floor.	Depth of concrete. in ins.
10 to 12.....	3	6 40	1.8	4
12 to 16.....	4	6 40	1.8	4½
16 to 20.....	4	7½ 40	2.25	4½
20 to 24.....	5	10 50	2.4	5½

For smaller spans than 10 ft. T-iron instead of I-beams will be used. In conclusion, it may be of interest to mention some tests recently made by the Austrian Society of Civil Engineers and Architects to determine the comparative strength of different systems of concrete arch floor construction. The Wuensch system was not included in these tests, but other tests made by the Hungarian Government show it to be far superior to the Monier system. These tests may be tabulated as follows:

	Brick.	Concrete.	Monier.	Melan.
Span.....	13½	13½	13½	13½
Rise.....	15¾	15¾	15¾	11
Thickness at crown.....	6	4	2⅞	3⅛
Lbs. iron used per sq. ft.....	...	...	8	4
Breaking load, lbs. per sq ft...	321½	737	839	3,360

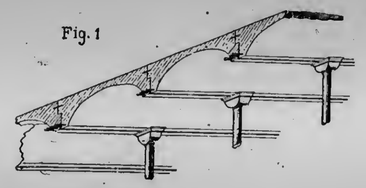
We are informed that in practice the relative strengths of the several arches when all are made of equal thickness are as follows: Brick arch, 1; concrete arch, 5; Monier arch, 16; Melan arch, 36. On the other hand, the relative thickness of different arches of the same strength would be: Brick arch, 12 ins.; concrete arch, 5 ins.; Monier arch, 3 ins.; Melan arch, 2 ins.

CONCRETE CONSTRUCTION.*

ON account of the small and very uncertain tensile strength of ordinary concrete it has appeared to be entirely unadapted for horizontal beams of floors or any parts of a structure subject to other than compressive force, nor did it appear a hopeful field for investigation and experiment. However, many efforts have been made during the past 20 years to unite the tensile strength of iron with the compressive strength of concrete in such a manner as to secure the whole value of each material for its respective position. These experiments demonstrated many years ago the feasibility of the union, but the methods were more or less complicated, and wasteful of the more expensive material, iron, for which reason little use was made by the discovery until Mr. Earnest L. Ransome, of our city, invented and applied plain, square, cold, twisted iron bars for this work, and demonstrated clearly that this simple process was perfect in its results, even showing a much greater advantage than the original tensile strength of the iron. The present paper will contain notes of the principal work that has been executed in this vicinity and that has come under the writer's observation within the past few years.

The first example in point of time is the Bourn & Wise wine cellar at St. Helena, erected in 1888. This building is 400 feet long, 75 feet wide, and three stories high. The entire site is cut into the side of a gentle sloping hill and so arranged as to have driveways 15 feet wide along the entire length at the rear and at the levels of both first and second floors, while beyond the driveways and retaining walls are 13 tunnels, 16 feet wide, penetrating the hill about 200 feet. On the site of the building and immediately surrounding it were an abundance of boulders, of very hard basaltic

Fig. 1

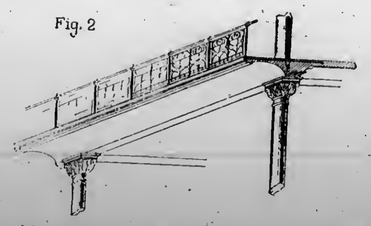


stone, quite unsuitable for rubble-stone work, owing to their rounding form, but excellent material for concrete when crushed; the finer materials were obtained in the form of gravel from a neighboring creek. A good quarry of the soft but durable volcanic tufa so common in Napa Valley was found within half a mile of the building, and as it could be quarried, hauled, and built into the walls for 17 cents per cubic foot it was employed for all walls and partitions of the building. The foundations, retaining walls, lining of tunnel entrances, and the main floor laid on the ground, were formed of concrete in the usual manner. The entire second floor, together with the driveway at that level, was constructed with concrete and twisted iron rods in the form of beams and elliptical arches, as shown in Fig. 1, and as here described. Two rows of iron columns 7 feet 4 inches on centre were placed lengthwise of the building, dividing the width into three sections of about 25 feet each. The floor was constructed with concrete beams 7 feet 4 inches on centers passing entirely across the building, with their soffits resting on the iron columns. The beams were 24 inches deep from soffit to surface of floor, and each had four 1¼ × 1¼-inch twisted iron rods near the bottom, with a vertical joint along the center of each beam, protected against leaking by a strip of lead embedded in each half of the beam. The arches between the beams were elliptical in form, and the concrete 5 inches thick at crown of arches.

The floor was estimated and intended to carry with safety on each beam, for each 25-foot section, two casks, each containing 2,000 gallons of wine, or a total weight, including cooperage, of 40,000 pounds, on each section 7′ 4″ × 25′, or about 220 pounds per square foot, uniformly distributed. The arrangement of the casks was intended to leave a gangway 8 feet wide in the center of each section, thus giving less stress than a uniformly distributed load. Before the building was finished one of these sections was tested with a uniformly distributed load of 300 pounds to a square foot, and produced a deflection of one-eighth of an inch at the center; on removing the load the beam returned to very nearly its original position. Since the building has been occupied many of the gangways have had tiers of large casks placed two in height along their entire length and smaller casks set between the upper bilges of the large casks, thus loading the floor largely in excess of its intended capacity. Implicit faith seems to be placed in this construction by those engaged upon it that it will carry anything that can be put on it. These floors have now been in use four or five years, and answer the purpose for which they were designed by making a strong and non-absorbing floor and assisting in keeping a uniform temperature throughout the building.

The next building of importance in which the writer employed concrete and iron floors was the California Academy of Sciences in this city. In this case a careful estimate of cost was made of the usual steel-beam and hollow tile construction, and compared with the cost of this method. The result was a saving of 50 cents per square foot, or $20,000 for the entire building,

Fig. 2



in favor of the concrete and twisted iron method. After due investigation the latter method was adopted by the Board of Directors and executed by Mr. Ransome. This work was subject to much adverse criticism by certain architects and builders, and some members of the Academy of Sciences, and persistent efforts were made by some to have the work condemned by fire wardens on the ground that it was not provided for in our valuable com-

* Abstract of a paper by George W. Percy, read February 9 before the San Francisco Chapter of the American Institute of Architects.

pilation known as the building ordinances. Several visits were made to inspect the work by parties connected with the Fire Department, but as they could not find anything about the construction that could be injured by fire, and had sense enough to perceive its great strength they declined to take any action in the matter. To satisfy all skeptics in regard to the strength of this work a test was made on a section of the second floor 22 feet span and 15 feet wide; this was loaded with gravel uniformly to 415 pounds to a square foot, and showed a deflection of one-eighth of an inch at the center of the beam. The load was left on this floor four weeks, and during that time many of the critics were invited to examine it. That very few availed themselves of the opportunity may indicate an unwillingness to have wrong opinions corrected. To those, however, who were directly interested in the work and had entertained honest doubts of its strength this test was satisfactory and conclusive.

The floors in this building were constructed with large beams about 15 feet apart and flat panels 8 inches thick between, with the plastering ap-

Fig. 3

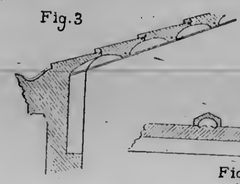


Fig. 4

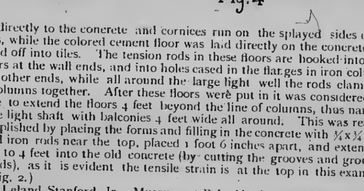


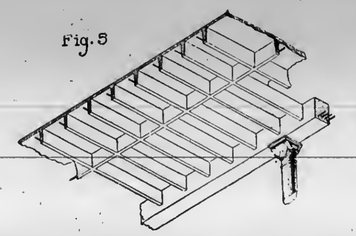
plied directly to the concrete and cornices run on the splayed sides of the beams, while the colored cement floor was laid directly on the concrete and marked off into tiles. The tension rods in these floors are hooked into wall anchors at the wall ends, and into holes cased in the flanges in iron columns at the other ends, while all around the large light well the rods clamp the iron columns together. After these floors were put in it was considered advisable to extend the floors 4 feet beyond the line of columns, thus narrowing the light shaft with balconies 4 feet wide all around. This was readily accomplished by placing the forms and filling in the concrete with ¾ × ¾-inch twisted iron rods near the top, placed 1 foot 6 inches apart, and extending from 2 to 4 feet into the old concrete (by cutting the grooves and grouting the rods), as it is evident the tensile strain is at the top in this example. (See Fig. 2.)

The Leland Stanford, Jr., Museum at Palo Alto is probably the largest most important building in the world constructed entirely of concrete. It was designed to have dressed San Jose sandstone for the external walls, backed up with brick, and to have brick partitions, with concrete floors. Owing to the great cost of stone work it was decided to build the walls of cement concrete colored to match sandstone used in the other university buildings, and to carry out the classic design first adopted. This led to making the entire structure, walls, partitions, floors, roof, and dome, of concrete, making it in that respect a unique building.

Having some knowledge of the disadvantages and defects natural to a monolithic building, such as result from the shrinkage and expansion and contraction of walls, floors, and roofs, several new experiments were tried to overcome them, with varying results of success and failure. It was thought to overcome the cracking of walls by inserting sheets of felting through the walls following the lines of the joints as near as practicable on each side of windows. The lapping bond of the concrete, however, proved too strong to allow the cracking to follow these joints; in most cases the weakest points were found at the openings, and small cracks appear from window sills to head above.

Joints were formed through the floors about 15 feet apart, and in most cases the cracking has followed these joints and been confined to them. To prevent the possibility of moisture penetrating through the walls, and also to render them less resonant, hollow spaces 5 inches in diameter were

Fig. 5



molded in the walls within two inches of the inside face, and with about 2 inches of concrete between them. These are successful for the primary object, and partially so for the secondary.

The roof being the greatest innovation, and the first attempt known to the writer of forming a finished and exposed roof entirely in concrete, required the greatest care and consideration. The result in form and appearance is shown by Figs. 3 and 4 and is described as follows: The roof is supported on iron trusses 10 feet on center and has a pitch of 20 degrees. The horizontal concrete beams rest on the iron rafters and with half arches form the horizontal lines of tiles about 2 feet 6 inches wide with joints lapping 2 inches and a strip of lead inserted as shown. Vertical joints are made through the concrete over each rafter with small channels on each side. These joints and channels are covered with the covering tiles shown on drawings, and similar rows of covering tiles are placed 2 feet 6 inches apart over the entire roof, thus forming a perfect representation of flat Grecian tile or marble roof. Notwithstanding the precautions taken, this roof presented several unexpected defects. The most serious proved to be in the Venetian red used for coloring matter and mixed with the cement. This material rendered the covering tiles absolutely worthless, many of them shocking like lumps of lime, and all were condemned and remade. The same material injured the general surface of the roof, rendering it porous and necessitating painting. The roof over the central pavilion, being hidden behind parapets, is made quite flat and covered with asphaltum and gravel over the concrete. This roof, with its low, flat dome, is without question the largest horizontal span in concrete to be found anywhere on earth, being 46 × 56 feet, the flat dome having all its ribs and rings of concrete, with the

panels or coffers filled with 1 inch thick glass, and weighing about 80,000 pounds. This structure, covering 21,000 feet, and containing over 1,100,000 cubic feet of space, and requiring about 260,000 cubic feet of concrete, was completed in seven months' time from the commencement of the foundations, and at a cost of about 18 cents per cubic foot of space. This the writer believes to be a very low figure for a thoroughly substantial and fire-proof building with marble stairs and wainscoting, cast iron window frames and sashes, and other parts equally enduring, and would call attention to the fact that concrete walls with iron rods embedded, when cracked are not in the bad condition of stone or brick walls without bond, but the iron ties are always good to prevent spreading or falling, while several methods may be devised for allowing free expansion and contraction without producing unsightly cracks. Some such method should be employed on all finished structures.

One of the rooms in this building was designed to be the receptable of many valuables, and to render it burglar-proof the floor, walls, and ceiling had copper wires embedded in the concrete not over 3 inches apart, forming a continuous circuit, and designed to strike an alarm bell at the university if any wire should be cut. This device has been in use at the United States Sub-Treasury vaults in this city for several years, and would be very effectual for prison walls and cells, as it would be almost impossible to cut a hole through strong concrete large enough to admit a man's body without cutting or breaking one or more of the wires, thereby giving an alarm.

Other important works have been executed in concrete in this vicinity, among which may be mentioned the girls' dormitory at the Sanford University, a three-story building completed in 90 days from the time the plans were ordered. Also the torpedo station on Goat Island, 80x250 feet, with walls about 30 inches high, built under the direction of Colonel Mendell: and the addition to the Borax Works at Alameda. In the latter the walls, interior columns, and all floors are concrete, and are remarkable for the lightness of the construction and great strength. These floors are constructed as shown in Fig. 5. In these floors the clear span is 20 feet. The floor consists of beams 4 inches wide at bottom, 5½ inches at top, and 1 foot 0 inches deep from bottom beam to top of finished floor. The beams are placed 2 feet 6 inches on center and the floor over the beams is only 3 inches thick. A section of this floor 10x20 feet was tested February 28, 1893, with the following results: Before testing there was a uniform load of 105 pounds to a square feet, when the scale was set to indicate deflection.

With 234 pounds per	square foot,	deflection.....	...	.1-16	inch.
" 273	"	"	"	.1-8	"
" 312	"	"	"	.1-8	"
" 390	"	"	"	.3-16	"
" 468	"	"	"	.3-16	"
" 551	"	"	"	¼	"

This deflection is in addition to any that may have existed with the initial load. In November, 1893, the writer visited the building with Mr. H. G. Jacobs, Government Inspector of Buildings, and in our presence a test was made on a section of the third floor, that was selected as an apparently weak spot owing to several cracks showing on the ceiling. A sliding rod was adjusted under the center of the beam. There was a distributed load of about 200 pounds per foot at the commencement; 225 pounds per foot additional were applied, and the deflection noted was less than one-sixteenth of an inch. This type of floor appears to be the best form yet devised for obtaining great strength with the minimum weight of concrete and least expense of carpenter work, the forms used being standard size to be used over again. With the present price of materials and labor such floors can be built with 20-foot span of safe strength for 250 pounds per square foot, and with finished cement surface, for 45 cents per square foot, and without the finished floor surface for 30 cents per square foot. Level plastered ceilings may readily be suspended from the beams and wood or tile floors laid over it, as in other methods of fireproof construction. This method of forming floors with the minimum of very rich concrete is lighter than the common method of steel beams and hollow tiles, for the same strength. The concrete should be composed of 1 part of Portland cement to 3 parts of selected aggregates.

The results given above are much better than could have been expected or hoped for a few years ago, and it is quite possible we have not yet reached the highest development.

In conclusion the writer would say, that while he does not think that concrete in any form is likely to take the place of stone, brick, and terra-cotta for architectural work, he feels quite certain that in combination with iron it is destined to fill a large place in the construction of buildings, and for warehouses, factories, wine cellars, etc., it is now the best and cheapest material for producing substantial and incombustible work.

OTTAWA.

(Correspondence of the CANADIAN ARCHITECT AND BUILDER.)

Messrs. Wm. Hodgson and W. C. Edy, architects, of Ottawa, at the request of the local Board of Health, have made an examination of the new Contageous Diseases Hospital buildings in course of erection on Porter's Island. They report that the buildings were not properly designed and that the material and workmanship employed in their construction are so inferior in quality that there is nothing to be done but to pull down the work that has been done and reconstruct it in a proper manner. The Local Board of Health have sent a copy of the report to Mr. C. F. Stalker, the architect of the buildings, with the request that he will make reply. In the meantime the Chairman of the Board has been authorized to stop the work, while the contractors are appealing to the Courts to either allow them to complete their contract or be released from it.

HALIFAX.

(Correspondence of the CANADIAN ARCHITECT AND BUILDER.)

Early in the present year regulations were adopted by the City Council for the plumbing work, and providing for the proper inspection of all work done within the city in future. Mr. E. W. W. Doane, City Engineer, was appointed Sanitary Superintendant, and Mr. Claude Donovan, Plumbing Inspector. From the annual reports of these officials it is learned that since the first of May, 1892, 469 houses have been connected with the main sewer, and 249 permits granted for building work. Some idea of the sanitary conditions hitherto existing may be inferred from the fact that out of 162 houses inspected on complaint not one was found in a sanitary condition. Referring to the sanitary condition of the city in the past, the Sanitary Superintendent says: "There were no inspectors, and closets were fitted up in every conceivable design and in all kinds of places without any provision for ventilation or particular attention to drainage. A favorite location was under the back stairs, from which position, under the mode of construction followed in the past, the poisonous gases from the drains easily found their way all over the house. The drain ran to a cesspit or an old stone drain in a filthy condition, and in some cases to the water pipe trench in the street. Often in some of the best houses there was no trap at all on the closet or waste pipe. These features and many others equally objectionable, may be noted on inspection of the plumbing work in three-fourths of the houses in the city, and yet our efforts to effect a reformation have been strenuously opposed. The plumbers are, I think, with one exception, willing and ready to do good work in accordance with our requirements."

FIRE-PROOF FLOORS.

In a paper recently read before the Civil Engineers' Club, of Cleveland, William Sabin, describes the forms of fire-proof flooring most commonly adopted in America. The oldest method was to place floor beams about 5 feet apart and turn a 4-inch brick arch between them, the beams being tied together to resist the thrust of the arches. The space above the arches was leveled up with concrete, in which were embedded strips of wood for the flooring. The plastering was applied directly to the bottom of the arches and over the flanges of the supporting beams. When exposed to a fire, however, it soon cracked off, and a special tile skewback is now used. Such a floor weighs about 70 pounds per square foot, exclusive of the weight of the floor beams. Its cost in America is about that of terra cotta. In this case the beams were placed 6 feet to 7 feet apart, the tiles being 10 inches deep, and the weight of the floor was reduced to 40 pounds per square foot and its cost to $1.34. A further reduction of weight was effected by the use of porous terra-cotta, obtained by mixing sawdust with the clay. The weight of the floor was thus brought down to 35 pounds per square foot, while its cost was $1.36.

In a test made at Denver, an arch of porous terra-cotta 4 feet wide and having a span of 5 feet, bore a load of 15,145 pounds with a deflection of 0.65 of an inch, and it took 11 blows of a weight of 134 pounds falling from a height of 6 to 8 feet to entirely destroy the arch.

Both systems of terra-cotta floor have successfully withstood severe fires. In a method of construction now being largely adopted, the span of the floor is increased to 12 feet, and it is supported by 12-inch I-beams. Between these beams is strained a galvanized wire net, said to be capable of carrying 1,000 pounds per square foot. A centre board is fixed below this net, and the space between it and the top of the floor filled with a very light concrete, made with crushed coke, cork, cement, and a little sand. This floor is 8 inches deep, the bottom flanges of the I-beams being protected by carrying the cement around them. Its weight is only 18 pounds per square foot, the deflection being only one-half inch. Its cost is about $1.05 per square foot.

MANUFACTURES AND MATERIALS

CAPE BRETON MARBLE.

A company has been organized to develop the extensive deposits of marble at Marble Mountain, Cape Breton. The directors of the company are: Rod Macdonald of Macdonald & Co., Geo. E. Francklyn, of S. Cunard & Co., Robie Uniacke, president Halifax Banking Co., James B. Hattie, of Hattie & Mylius, Ald. Mosher, Henry Saunders, and C. Hobrecker. The directors have elected the following officers to manage the affairs of the company: President, Rod Macdonald; vice-president, George E. Franklyn; sec.-treasurer, Geo. Hattie.

The capital required to develop the property has been subscribed, and work is to be carried on under the supervision of D. D. MacLachlan, manager.

The marble which is to be worked may be classified as follows: Pure white, variegated blue and white, pink, blue, dappled and water white.

Nature has made it possible to produce this marble very cheaply. Its location near to a good place of shipment, while no power but its own weight is necessary to move the marble from the quarries to the wharf; its proximity to the Cape Breton coal fields; its perfect natural drainage and the abundance of sand for sawing in the immediate neighbourhood are advantages seldom combined.

Active operations have been commenced. A steam channeling machine, mill machinery and castings for derricks are all on the ground and the erection of a mill and other necessary buildings will be carried forward as energetically as possible. A tramway down the mountain side from the quarries to the wharf — a distance of about 1,200 feet — will shortly be completed.

The company expect that within the course of three months they will be able to place their marble on the market.

A road in course of construction will bring the quarry within five miles of the railway. Samples sent to Great Britain have given great satisfaction. The quarry has also been examined and approved by an expert, Mr. Underhill, of Vermont.

A handsomely printed and illustrated catalogue relating to Wilson's inside and outside rolling blinds, has been received from Mr. Geo. Chatworthy, Toronto, Canadian agent.

The Crown Pressed Brick Company of Ottawa are applying for incorporation; capital stock $100,000. The provisional directors are G. W. McCullough, H. L. Corbell, J. J. B. Butterworth, all of Ottawa, and H. Mills, of Ormstown, Que.

MODERN EXPLOSIVES.

The compositions of some of the modern high explosives are as follows:

Dynamite.—Seventy-five parts of nitro-glycerine and 25 of infusorial earth.

Dualine.—Eighty parts nitro-glycerine and 20 of nitro-cellulose (gun cotton).

Rendrock.—Forty parts nitro-glycerine, 40 of nitrate of potash or soda, 13 of cellulose and 7 of paraffine.

Giant Powder.—Thirty-six parts of nitro-glycerine, 48 of nitrate of potash or soda, 8 of sulphur, and 8 of resin or charcoal.

Mica Powder.—Fifty-two parts of nitro-glycerine and 48 of pulverized mica.

Tonite.—Fifty-two and one-half parts of gun cotton and 47½ parts of nitrate of baryta.

Blasting Gelatine.—Ninety-two parts of nitro-glycerine and eight of gun cotton.

Atlas Powder.—Seventy-five parts of nitro-glycerine, 21 of wood fiber, 2 of carbonate of magnesia, and 2 of nitrate of soda.

Rackback.—77.7 parts of chlorate of potash and 22.3 of nitro-benzol.

It will be noticed that nearly all the above explosives are composed principally of nitro glycerine; and it is probable that in most cases the other ingredients only act as absorbents for this liquid, and really add nothing to the explosive force. The decomposition of nitro-glycerine is practically instantaneous, and the slower acting nitrates and hydro-carbons must be left far behind when the mass is exploded. The power of all these substances is due to the paradoxical element, nitrogen, which is by itself the most neutral and inactive of all the elements, but, when forced into chemical combination, usually confers an element of weakness upon the entire molecule of which it forms a part.

LEGAL.

In the case of Lavoie vs. Ouimet, which came up for hearing recently in the Superior Court at Montreal, the plaintiff asked that the defendant be ordered to remove a certain building which plaintiff alleged defendant had transferred from his (defendant's) house, and placed at one side thereof, and in close proximity to the line and division between their respective properties. The plaintiff alleged that by a deed of sale of the property in 1884 the defendant especially bound himself never to erect any building in proximity to the portion of the property thereby sold by defendant to plaintiff, which might be injurious to plaintiff in any manner whatsoever. The pretension of the plaintiff was that, by removing the building and placing it where it now stood, the defendant had violated the stipulation of the deed, the building shutting off plaintiff's view of the main road and spoiling the appearance of his property. The court was of opinion that the weight of evidence sustained the plaintiff's pretension, and the judgment ordered the defendant to remove the building, or, in his default so to do, that it be removed by the officers of the court.

PUBLICATIONS.

The Canadian Office and School Furniture Co., of Preston, Ont., have issued a new catalogue, which is attractively printed and contains numerous illustrations of office furniture of various kinds.

Our thanks are due and are hereby tendered to Mr. H. Saywand, Secretary of the National Association of Builders of the United States, for a substantially bound copy of the proceedings of the eighth annual convention of that organization.

Dr. Albert Shaw, editor of the Review of Reviews, contributes to the June number of that periodical an interesting four page illustrated description of the new National Library at Washington and a pen-picture of the Librarian, Mr. Ainsworth R. Spofford. The new building is fast nearing completion, and another year will probably witness its occupancy by the greatest collection of books on this side of the Atlantic.

VALUE OF A LABORER IN CONTRACT WORK.

There is no article that enters into contract work of so uncertain value as that of labor. In all the multitudinous things to be done on a large contract, labour is one of the most important for various reasons. The conditions of every kind of work change so that labor values can not be accurately gauged. The times of year in which work is done, the class of work, and the experience of the laborer at the different kinds of work, all make a case where the discrimination of the contractor must come into play to arrange a system of gauging the value of a man's labor on any given work. Some contractors contend that skilled laborers at advanced prices pay better than hiring indiscriminately any and every class of men who present themselves for labor work. In hiring untried laborers much can be saved by having a live foreman, who is good at forcing the men to work; yet there are men of so stupid a disposition that getting work out of them is next to impossible. A contractor of wide experience says that he can, by intuition, tell in a short time just what men are capable of doing, and that he can detect a shirk in short order; as soon as he finds a man inclined to shirk, that he discharges him at once, and finds that it has a salutary effect upon the others. The difference in the amount of labor that one man can perform, compared with another of the same physical strength, is in the same ratio when one accounts for the payment of the two men, that from ten to sixty minutes loss per day on a laborer would foot up in the course of a week. In employing a large number of men, day in and day out, there is no doubt a great variety of difference in the results of the labor performed, and those results depend very largely upon the study that employers and foremen give to the subject of labor. The loss of 10 cents per day on a man's labor does not apparently amount to much; but on a hundred men it is $10. Now 10 cents is a small amount to reckon as difference in value of one over another for 25 cents would be nearer the mark. One can see when he pays close attention to the labor on his contracts where one contractor comes out ahead of another by close attention to labor details. Quantities and qualities of material in contract work can be valued to the penny but labor cannot.—Eastern Contractor.

USEFUL HINTS.

It is officially calculated in New York that the tall buildings erected in lower Broadway up to date, have added seventy-five acres to the business area of New York city above the sixth story.

Concrete sidewalks should be laid four inches thick, in two courses; first or bottom course three inches, second or finishing course one inch thick. The top should be laid before bottom is set. Prepare foundation on which to put concrete in good coarse gravel or chip stone, well rammed or levelled. Proportion for bottom, one part cement, four parts clean sharp gravel, mixing cement and gravel thoroughly in the dry state, and sufficient water from a sprinkler to make a dry mortar, place at once and thoroughly ram down. For top mix one part cement and one part clean sharp sand; mix well before adding water, add water as above to the consistency of plastic mortar.

A STOPPING for wood, sometimes called beaumantique, can be made as follows: Put one tablespoonful of shellac, one teaspoonful powdered resin, a piece of bees-wax the size of a walnut, into a cup or iron pot, and set on the stove or in the oven until melted. For mahogany, add to it a little Venetian red, to match up the wood; for oak, add yellow ochre; for ebony or rosewood, add lampblack; mix it well up. It can be used while liquid, or it can be made into sticks like sealing wax, by pouring it on to a board, and rolling it with another board slightly warmed. If made up in sticks in this way, it is a good plan to have a variety of colors. When using, melt it over a lighted candle or gaslight, and run it into the place to be repaired; level off with chisel, and smooth down with glass-paper.

MICROSCOPICAL investigation has proved that the pores of wood invite the passage of moisture in the direction of the timber's growth, but repel it in the opposite direction. This accounts for a phenomenon which is often noticed, and which puzzles a good many people, namely, why two pieces of timber sawn from the same section of a tree sometimes appear to possess very variable degrees of durability. If the wood, say of a gate post, is placed right end up, the moisture in the soil will affect it, but the rain falling on the top will do little harm; if, on the other hand, the butt end of the tree is uppermost, the top of the post will decay, because the moisture of the atmosphere will penetrate the pores of the wood more rapidly in this position. Many people have noticed that the staves of a wooden tub appear to absorb moisture irregularly, some getting quite sodden while others remain comparatively dry, and apparently almost impervious to moisture. In this case the dry staves are in the position in which the tree grew, while the saturated ones are reversed.

CREDIT VALLEY BROWN STONE

From Carroll & Vick's No. 6 Quarry, Credit Forks, Ont.

SANDSTONE, fine grained, reddish brown. Contains quartz, and a little felspar and mica. The stone is in beds of four feet and under, and can be handled in pieces up to five tons. Quarry 300 yards from Railway.

Specimen.	Section under Pressure	Height.	Crushing Load.	Crushing Stress per sq. in.	Average Crushing Stress per Square Inch
	Ins.	Ins.	Pds.	Pds.	Pds.
A	.....	.....	.....	.....	
B	2⅞ × 3	2⅞	131,000	15,188	
C	2 1/16 × 3	2⅞	130,000	14,751	
D	3 × 3	2⅞	133,000	14,777	14,905

14,905 pounds is the average crushing strength per square inch of our Credit Valley Brown Stone.

The highest standard of test attained by any pure Sandstone in America.

IN confirmation of the facts above stated, we have pleasure in directing your attention to the accompanying table, showing the result of the test of our stone, in connection with the series of tests of building stones conducted in 1872 at the School of Practical Science, Toronto, under the direction of a committee of the Ontario Association of Architects.

By referring to the results of the tests above mentioned, it will be seen that the average crushing stress of the majority of Canadian and American sandstones is far below that of ours, the difference in our favor ranging from 75 to 50 per cent.

The Credit Valley Brown Stone, owing to its modest tone, harmonizes beautifully with red or cream colored brick.

It has been reported that there is difficulty in obtaining Credit Valley Brown Stone. To correct this mistaken notion, we wish to state to architects and the public that we have a large quantity of stone ready to ship on the shortest notice, which can be followed up with an unlimited supply. Last year we made extensive additions to our plant and opened up new quarries and mines, and will supply promptly all orders given to us or our agents.

CANADIAN ARCHITECT AND BUILDER.

VOL. VII.—NO. 7. JULY, 1894 PRICE 20 CENTS $2.00 PER YEAR.

THE
CANADIAN ARCHITECT AND BUILDER,
A Monthly Journal of Modern Constructive Methods.
(With a Weekly Intermediate Edition—The CANADIAN CONTRACT RECORD).

PUBLISHED ON THE THIRD THURSDAY IN EACH MONTH IN THE INTEREST OF
ARCHITECTS, CIVIL AND SANITARY ENGINEERS, PLUMBERS, DECORATORS, BUILDERS, CONTRACTORS, AND MANUFACTURERS OF AND DEALERS IN BUILDING MATERIALS AND APPLIANCES.

C. H. MORTIMER, Publisher,
Confederation Life Building, - TORONTO, CANADA.
Telephone 2362.
Branch Office: NEW YORK LIFE INSURANCE BUILDING, MONTREAL.
Bell Telephone 2259.

SUBSCRIPTIONS.

The CANADIAN ARCHITECT AND BUILDER will be mailed to any address in Canada or the United States for $2.00 per year. The price to subscribers in foreign countries, is $2.50. Subscriptions are payable in advance. The paper will be discontinued at expiration of term paid for, if so stipulated by the subscriber; but where no such understanding exists, will be continued until instructions to discontinue are received and all arrearages paid.

ADVERTISEMENTS.

Prices for advertisements sent promptly on application. Orders for advertisements should reach the office of publication not later than the 12th day of the month, and changes of advertisements not later than the 5th day of the month.

EDITOR'S ANNOUNCEMENTS.

Contributions of technical value to the persons in whose interests this journal is published, are cordially invited. Subscribers are also requested to forward newspaper clippings or written items of interest from their respective localities.

Subscribers who may change their address should give prompt notice of same. In doing so, give both old and new address. Notify the publisher of any irregularity in delivery of paper.

THE attention of the City Council of Toronto has recently been called to the fact that repairs are urgently required for the preservation of the residence of the late Mr. Howard, the donor of Howard Park. Mr. Howard, who was an enthusiastic antiquarian, bequeathed to the city not only many acres of beautiful park lands, but also his residence, stables, etc., with their interesting and valuable contents. To allow these to perish through neglect would show a lack of appreciation of the donor's generosity which should be sufficient to discourage the giving of like public bequests in the future.

IF we are to judge by the slim attendance at the public meeting called in Toronto recently to discuss the construction of a trunk sewer, the citizens see no pressing necessity for the project being undertaken at present. That a better method of sewage disposal than the existing one is required cannot be questioned. A still more important matter at the present time, however, is the adoption and carrying out of means for increasing the water supply and for ensuring its purity. If the city's financial position will not warrant the immediate commencement of both these undertakings, then precedence should certainly be given to the one last mentioned, upon the carrying out of which the health of the citizens so largely depends.

ON another page of this paper is printed the provisions of a by-law for the regulation of plumbing and drainage work in the city of Montreal. This law, which has been under consideration for the past two years, finally passed the Council on the 24th of June. It appears to have been carefully framed, and will no doubt be the means of vastly improving the standard of plumbing and drainage work in the future. From our knowledge of of the sanitary condition of the city, an ordinance of this kind has long been a necessity. It is gratifying to observe one Canadian city after another thus providing means for the protection of the public health. If action had been taken in this direction years ago it would have resulted in the preservation of thousands of lives.

OUR attention has been attracted by an account of the annual meeting of the Whitby Hedge Co., Ltd., to a new and apparently profitable line of business the planting of hedges in which the above company are the pioneers in Canada. The company show a substantial surplus on the business already done, and unfinished contracts amounting to upwards of $12,000. Judging from its location and the personnel of its managers, we presume this company's operations are confined to the rural districts. There is a growing opportunity in the cities also for work of this character. It is gratifying to note these evidences of the growth of the artistic instinct and sentiment among all classes of our people. As a result, the charm of landscape for which England is famed may possibly in future characterize Canada also.

THERE was recently published the statement that the cost of building operations in Winnipeg this season would be nearly double that of 1893, or between a million and a half and two million dollars. In view of the general commercial depression, we read this statement with surprise. Its authenticity is now being called in question, and it is alleged to have had its source in the office of an enterprising real estate firm, whose methods are not unknown in some of our eastern cities. Building operations in Winnipeg are on a moderate scale, and are not likely to exceed the record of last year. British Columbia advices state that a quiet season is being experienced. Works on the new

Legislative buildings at Victoria is said to be progressing satisfactorily. On the ground that in the erection of these buildings American materials and workmen were discriminated against, an effort is being made by the Trades Council of Tacoma, to prevent Mr. R. L. Fox, a British subject, who secured the contract for granite work on the Port Orchard dry dock, from using Nelson Island, B. C., granite in the work.

DOUBTLESS as the result of representations made from time to time by the Architectural Associations of Ontario and Quebec, it is gratifying to learn that the Government has resolved to change the method of appraising the value of architectural plans imported for use in the erection of buildings in Canada. We are informed that new instructions have lately been issued by the Government to customs officials, under which architectural plans passing through the customs will in future be charged a duty based on the cost of the building to be erected. It has likewise been stated, though with what authority we know not, that the new regulations are to be retroactive, and that under them duty will be collected on the cost of the Ontario Legislative buildings, the Toronto Board of Trade, and other buildings erected during recent years from the plans of foreign architects.

THERE is no other class of work in which contractors are obliged to exercise so much ingenuity, good judgment and care as in alterations to existing buildings, which require shoring, underpinning, etc. It is quite common to see the architecture of heavy business blocks and entire streets entirely changed in this way, and in many cases it affords a comparatively cheap means of modernizing property which would otherwise be unattractive and in little demand for business purposes. The calls for this kind of work are becoming more frequent, and it cannot be too carefully studied by all who wish to make themselves competent for any emergency that may arise in their business. We publish in another part of this number a few examples of such work, and hope to follow them with others equally or more interesting.

AN act passed by the Legislative Assembly of Ontario at its last session provides one of the simplest, cheapest and speediest methods that has yet been devised for the settlement of controversies by arbitration. The Board of Trade in any city of 30,000 inhabitants may elect 25 members of a Board of Arbitration to be chosen from 30 or more names selected by the Council of the Board of Trade. Membership in the Board of Trade is not a necessary qualification for the Board of Arbitration. Persons submitting a case may select one, two or three members of the Board of Arbitration to hear and decide the case. Sittings may be entirely private unless otherwise agreed, and unless the time be enlarged by agreement, all awards shall be made within twenty-one days after the submission has been signed. Arbitrators can compel attendance of witnesses on oath and have other powers similar to those in other arbitrations. There is also provision for the submission and award being made a rule of court.

ONE of the most difficult problems that architects have to consider is how to educate the public to a better understanding of what an architect's duties are, and the necessity and value of his services in connection with the erection of buildings. Many people have a hazy sort of idea that architects have something to do with very large or public work, but would never dream that they needed an architect to assist them in building a house, even of considerable cost, much less a small or cheap house such as they imagine "anybody" could successfully manage. How often has the remark been made, "Why, you wouldn't pay for an architect for a house costing so little as that, would you?" And how often persons have started out to save the architect's fee and lost twice as much by lack of his services, to say nothing of the wrangling and worry incident to such efforts. We hope to see this question a live one among members of the Architectural Associations when the season for outings is over, and would be pleased to receive suggestions as to the legitimate means which might be employed to better acquaint the public with the nature and value of the services which an architect should render to his clients.

ATTENTION is directed to the testimonial letter printed on another page of this paper, showing the value of the CANADIAN ARCHITECT AND BUILDER as a medium through which to advertise materials for the use of architects and builders. We have on file and shall publish from time to time a number of other letters from advertisers handling various lines of goods, all bearing testimony to the wide circulation of this Journal and to the fact that the most satisfactory results have followed its use. There are still some lines of business which should be represented in our advertisement pages, as indicated by the following enquiry just received from an architect in a western city: "Will you kindly forward to me by return mail, the names of some parties who would tender on wiring a building for incandescent lighting. I have not the time to advertise in the CONTRACT RECORD, therefore I have asked this favor." Architects and builders will oblige the publisher of the ARCHITECT AND BUILDER by frequently scanning the advertisement pages, and by communicating with us when requiring materials which they do not find advertised.

DURING the past month the people of the United States have been wrought up to the highest pitch of anxiety through a succession of strikes centering in and around Chicago. As usual Canada has been pursuing the even tenor of her way, but while we have been favored with freedom from the turmoil which has engaged our neighbors, we must not be unmindful of the signs of the times and the fact that the question of our continued prosperity may be affected at any time by the development of a larger sympathy with the situation in other countries. The civilized world is groping about for some means of allaying the dissensions between labor and capital. England is well in advance of America in dealing with this question. In the States present progress amounts to little more than a proof that there is a labor question which must be settled, or at least brought nearer to a settlement than it is now, and with as little delay as possible. If this is not done by peaceful agitation and combined effort on the part of all interested, there is every indication that still greater trouble will follow. The relations between labor and capital will not stand many such strains as the recent occurrences in Chicago. None have more at stake in this question than the builders, and they should have as much influence as any class of men for its intelligent treatment. Labor organizations are still too ready to resort to strikes. Peace between capital and labor can never be maintained except by mutual concessions and constant readjustment to meet new conditions. This must be brought about through earnest study and in compliance with natural laws. To this end contractors, material men and tradesmen should meet each other and cultivate at all times a feeling of mutual interest and good will. In this way they would wield a more powerful influence for holding men in check and for preventing such frequent resort to strikes with their sure accompaniments of violence and other aggravated evils. Of all the remedies proposed for removing the differences between labor and capital, arbitration stands to the front as meeting with the greatest amount of favor. It will not be found a universal remedy, as some apparently believe, but it will be very helpful as an intermediate step in some cases, and will become the established usage in others. In all business carried on under public franchises, and largely for public convenience, such as railway and telegraph operation, government should make such regulations as would prevent any set of employees going on strike or leaving their work in such numbers or manner as to interfere with the usual facilities for the performance of public service. For business involving only private interests the best results will come from the recognition of mutuality of interest between employers and employees. When employers and employees shall be willing to meet each other in a spirit of fairness and friendliness, they will be able to work together on a common basis to secure legislation tending to lessen the differences which now frequently arise, and secure their equitable adjustment without recourse to strikes. The whole subject is worthy of the serious attention of all business people. The necessity for its consideration is imperative.

The days of the "steeple" are numbered in New York. The many tall buildings recently and still being erected in the city completely dwarf the former landmarks.

The Ratepayers Association has resolved to petition the legislature to amend the city charter, so as to disqualify as voters at municipal elections every person in the employ of the city or having an interest in any contract with the city.

MASONIC HALL COMPETITION.

The new Masonic Temple which is to be erected on Dorchester street, from designs by Mr. Robert Brown, architect, of this city, will have a frontage of 51 feet and a depth of 109 feet. On each side of the entrance there will be stores, and in the rear a concert hall. The first floor will be fitted up as offices and assembly hall; the second floor as club and refreshment rooms, and the top floor for lodge rooms. In the basement will be the caretaker's quarters, billiard room and vaults. The cost of the building will be about $60,000.

Following is a copy of the report of Mr. Hutchison, the expert appointed to judge the plans submitted in the above competition:—

MONTREAL, June 25th, 1894.

Will. H. White, Esq.,
Secretary Masonic Temple Company.

DEAR SIR,—I beg to report that I have examined the several competition designs sent in for proposed Temple Building on Dorchester Street.

For this competition eleven designs were submitted under nine mottos as follows:—"Shield," seal in red wax with the motto "Touch Not the Cat but a Glove"; "Complete," (three different designs); "Beta"; "Forty-seventh problem of Euclid"; "Try"; "Inter Nos"; "Wasp"; "Ich Dien."

A preliminary examination of the several designs showed that the competition for the first and second place lay between two designs—one designated by a shield and the other by a seal in red wax.

After a careful and minute examination of these designs and a comparison of the merits of each, I came to the conclusion that the design bearing the motto of a shield should be ranked first in merit, and the design bearing a red seal with the inscription "Touch Not the Cat but a Glove," should rank second.

In arriving at this conclusion I have taken into consideration that the author of the second design adhered strictly to the conditions respecting the placing of the two largest lodge rooms in the rear of the upper story of the building, and the smaller in the front, while the author of design No. 1 took the liberty of placing one of the large lodge rooms in front: this change, however, gave him no advantage over the author of design No. 2, and the selection of his design as first is made without awarding him any superiority for this arrangement.

The selection of the design as third in merit I found a more difficult task, as three of the designs approached so nearly in merit that it was difficult to determine which was best. After a careful examination I concluded that one of the designs submitted under the motto "Complete," which I have for the purpose of distinguishing it from the two designs by the same author, marked in pencil as "No. 1," is third in merit.

I have the honor to be,
Your obedient servant,
(Sgd.) ALEX. C. HUTCHISON.

ORGANIZATION OF PLUMBERS.

A general meeting of the master plumbers of this city was held in the "Monument National" building on Thursday evening, the 12th inst., for the purpose of organizing themselves into an association to raise the standard of their profession. Messrs. J. W. Hughes, W. M. Briggs, P. J. Carroll, John Date, Jas. A. Sadlier, Wm. Britton, Jos. Turcotte, John Burns, P. C. Jacotel, J. Jacotel, C. St. Denis, G. W. Henders, Albert Cardinal, H. Paddon, A. Sicotte were present, amongst many others whose names it has been impossible to procure.

On motion of Mr. Hughes, Mr. P. C. Jacotel took the chair. In brief terms the chairman addressed the meeting in French, stating the object for which it had been called; and requested Mr. Hughes to address the meeting in English.

Mr. Hughes said that a by-law similar to those existing in the principal cities of the United States to regulate plumbing in Montreal had been needed for a long time. He was glad to say that such a by-law had been recently passed, though it was not up to what master plumbers would have liked it to be.

A committee was appointed to consider the plumbing by-law adopted by the City Council and to report at an early date. The election of officers for the projected association was deferred to a future meeting. This association proposes to embrace all the master plumbers in the province of Quebec, with headquarters in Montreal, and branches in the principal cities of the province.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.

At a Council meeting of the Association of Architects of the Province of Quebec held on Thursday, the 12th inst., it was resolved to call a general meeting of the members of the Association, which will be of great importance to members, as it is proposed to discuss the advisability of applying to the Legislature for the purpose of making changes in the charter of the Association.

STUDENTS' DEPARTMENT.

USEFUL HINTS.

SQUARING UP LINES.—In drawing the lines for a foundation, or stretching them overhead for a shafting, a paper of pins comes in handy, to locate positions on the lines. All that is required is to thrust one through the line every time a point is to be located, and it can be easily done, in a moment, as close to the mark as anyone can work on a drawing board. It may take a few moments to square a set of cross lines on the six, eight and ten principle, when there is to be a ten-foot pole supported by three assistants, reaching out from whatever they may be able to stand upon, as every change in a cross line disturbs all the measurements, but when once adjusted all further lines can be laid out by direct measurements, and the rest of the angles will take care of themselves.

SEASONING WOOD.—Growing wood contains in winter about 50 per cent. of water, in March and April 46 and 48 per cent. in the next three months, with but little variation up to November. Timber dried in the air holds from 20 to 25 per cent. of water; never less than 10 per cent. Wood dried by artificial means until all the moisture is expelled, is deprived of its elasticity, and becomes brittle. If the natural qualities of the wood are to be preserved, the drying must begin at a moderate heat, and be carried on very slowly. For the drying of small pieces of wood, such as are used by joiners or cabinet makers, a bath of dry sand, heated to a temperature not exceeding one hundred degrees, is recommended. The sand diffuses the heat, and absorbs moisture, but it must be cold when the wood is first buried therein.

EFFECT OF HEAT ON LEAD PIPES.—Text-books contain a great deal of useful information, no doubt, but they fail to give a vast amount of knowledge which is required in practice. Where, for example, do we find any mention of the effect of heat on lead pipes? In the case of a recent electric lighting installation, exhaust steam by some means found its way into the ventilating and soil pipes leaking to the drains. One of the first evidences of this was found in the warping of all lead pipes so used. It appears that the heat of the exhaust steam caused the lead pipes to expand and warp, but when the steam was entirely prevented from entering the drains the lead would not contract, and all such pipes had to be straightened by hand. This is a point which embryo engineers would do well to keep in mind, as each time the pipes were heated they expanded, but in no case did they show any signs of coming back to their normal condition.—Industries and Iron.

SAND IN MORTAR.

It was the opinion of Vituvius that pit sands were preferable for mortar, but he says that they must be freshly dug, otherwise they are decomposed by the action of the atmosphere and become earthy, and in this state they make bad mortars. Alberti, Palladio, Philibert, Delorme, Blondel and some other writers agree in these opinions, but Belidor thinks that river sand is best, and that it should be sharp. Palladio considers that white sands are worst. Belidor states that color has nothing to do with the matter. Rondelet, in consequence of these contradictory opinions, made experiments himself on the subject, with the following results:—(1) That the glassy or quartzose sands form with lime a weaker mortar than mixed sands, and that such mortar is longer drying. (2) That pit sand produces a better mortar than that made with river sand composed of grains of the same size. He did not find that the sharpest (*plus arides*) sands made the best mortar but thought that of sands of the same kind those which were deepest in colour, excepting the yellow, were to be preferred. The best sands, he states, are such as hold a middle place between those which are very plastic and very sharp. On comparing mortars made with freshly dug sand washed and dried in the sun, the sharp (*arides*) grains only being left, he found that the first acquired the greatest hardness, and that mortar made with very fine sand did not harden so well as that made with sand of a moderate-sized grain.

All these authors considered sea sand the worst, but Alberti mentions an exception. The sea sand from the neighborhood of Salerno he found to be as good as the best pit sand.

A FAILURE OF CAST IRON COLUMNS.

Major-General Hutchison's report to the Board of Trade, of London, England, gives the result of his enquiry into the accident which occurred on the 12th of December, at Portsmouth Harbor Station, when the roof covering the arrival island-platform was blown down by a high gust of wind just as a train was leaving. Several persons were injured, one very seriously. The fall of the roof must, Major General Hutchison says, in the absence of any other probable cause, be attributed to the effect of a sudden gust of wind during the prevalence of a gale. The zinc roof covering did not give way, but the wind pressure was transmitted toward the base of the cast iron columns—a double row of which supported the roof—with the result that one (or more) of these was at once broken off four feet above its base (which was bolted down to wrought iron cross girders, connecting the cast iron columns employed in the structure of the station); this being immediately followed by the similar fracture of the whole of the forty-nine remaining columns, and the fall of the roof. The columns were all broken in two places, the two points of fracture being in each column almost identical. The thickness of metal was intended to have been uniformly $\frac{1}{2}$ inch, and it must have been either from a deficiency in this thickness or from a flaw in the casting that the force of the wind was able to break a column thus weakened. The evidences of the witnesses does not lead to the impression that they had felt the force of the wind very excessive when the roof fell. Theoretically these columns should have been able to sustain a far greater pressure than they were ever likely to have been exposed to.

"A Draughtsman" writes to the Ottawa Journal urging the formation of an Architectural Sketch Club, on lines similar to the Toronto club. "Draughtsman" is apparently unaware that the Toronto Sketch Club has ceased to be. It should be possible for clubs of this character to be organized and maintain a useful existence in several of the leading cities of Canada.

TORONTO BUILDERS' EXCHANGE.

WE are pleased to learn that the Toronto Builders' Exchange are again holding their annual excursion to Lake Island Park, Wilson, N. Y., on Friday the 27th inst. As the Committee are making every possible arrangement for the pleasure and comfort of the party, this will, no doubt, be one of the most enjoyable trips of the season.

We understand that the steamer "Garden City" (which has been chartered by the committee) will leave Yonge street wharf at 10 a.m. on the above mentioned date, the price of tickets being 50 cents, and 20 cents for children. The members of the Exchange extend a hearty invitation to all their friends to accompany them upon the trip.

ESTIMATES AND QUANTITIES.

THERE is generally a considerable difference to be noticed between an estimate prepared by a builder from a set of drawings and a specification and one which is based upon bills of quantities prepared by a regular surveyor. It is often assumed that a builder can sail nearer to the wind than a surveyor; that he is not under the same necessity for allowing margins of safety, and that, in fact, as he makes any omissions at his own risk, he knows how to compensate himself for such lapses of forethought. Hence, in small works, when an estimate has been accepted on a builder's own quantities, the architect is more than usually on his guard against making allowances for extras. When there is a disagreement in such cases, the amount in dispute is often so trifling that the builder ends by yielding the point and accepting the architect's award. If the architect be a fair-minded man, he

NEW LEGISLATIVE BUILDINGS, VICTORIA, B. C.
F. M. RATTENBURY, ARCHITECT.

will endeavour to adjudicate impartially between the builder and the building owner, allowing the interests of neither to gain any undue ascendancy. This, however, is an extremely difficult thing to do. Setting aside the fact that an architect's own interests are mainly identical with those of his client—a fact which, it is fair to say, does not influence the conduct of most professional men—how does the question usually present itself to the mind of an architect? On one hand there is the client, a man unversed in the technicalities of building, and therefore completely at the mercy of those acquainted with all its mysteries. On the other hand, is the builder, with his own special, practical knowledge, which on some points may exceed that of the architect, and with one object before him—that of carrying on his business with the greatest amount of profit to himself. It is then assumed at once that the client alone stands in need of protection; and so it often happens that an architect becomes virtually his client's advocate, instead of maintaining a judicial attitude between him and the builder.

When a builder commences making an estimate without a previously-prepared bill of quantities, he has an amount of labour thrown upon him for which he can claim no remuneration, and which, in a competition, may prove utterly unfruitful. In taking off quantities, although he will probably adopt more simple and rough and ready methods than would be found convenient for a surveyor, his task becomes really more complex. Instead of taking off a number of dimensions, to be subsequently squared or cubed, abstracted, and brought into bill, he may be seen examining the drawings with knitted brows, going through mental calculations, and occasionally jotting down rough notes. He "lumps" many of his items, considering in his mind the quantity of materials required, the markets where they can be obtained, the cost of carriage, the amount and quality of labour involved, and the profit for which it will be worth his while to undertake the work. Such methods of procedure, so far from being haphazard, demand the exercise of more thought, and bring into play a larger amount of practical knowledge than is generally realized. The items which are "lumped" in a surveyor's bill require an equal amount of careful consideration in pricing, but these items are comparatively few.

In estimating the cost of carving and other ornamental work, the builder often runs considerable risk, unless there is a plentiful supply of large scale details to form the basis of his estimate, or unless he is thoroughly familiar with the style of work which the architect is in the habit of carrying out. In an open competition, when the lowest tender is to be accepted, there is little doubt that differences between estimates are often largely due to vague drawings or the absence of provisional sums for ornamental work in the specification. Marginal sketches in the latter are extremely useful to an estimator, and might be introduced more extensively with advantage, especially in these days of rapid work, when it often happens that there is not time to draw many details before the contract is signed. Architects are usually ready enough to furnish a builder with all the information they can command, and to afford him every facility in preparing his estimate; but time rarely permits of this being done in a thoroughly satisfactory manner to all concerned. Sometimes a builder is allowed two days in which to estimate the cost of a work. He cannot be expected, under such circumstances, to take off quantities in any true sense of the words, and thus finds himself driven to adopt expedients which only very sound knowledge can make reliable. An inexperienced man, says the Building Times, who secures a contract in a competition may well doubt if he has not engaged in an unprofitable undertaking, and may even come to envy those who have given time and thought to the preparation of estimates which have not been accepted.

When an architect is carrying out a work for which the estimate is based upon builders' quantities, he should bear in mind such circumstances as we have endeavoured to delineate. As a matter of fact, such estimates often come out much cheaper than those which are made from bills of quantities supplied by a surveyor. In some cases builders have been known to make little or no profit upon the original contract, and have even sustained losses over extras and omissions. In these days of bad trade it is indeed hard to be presented with the alternative of standing idle or of working to no advantage, and every consideration ought to be shown, in carrying out the details of a work, to those whose toils are but too seldom adequately rewarded.

LEGAL.

Mr. McLea Walbank, architect, of Montreal, designed a chimney for the Royal Electric Co., of that city. The chimney was built by Mr. Wand, contractor, and is alleged to have proved defective. The company brought action for $1,281 damages against the contractor, who in turn took action in warranty against Mr. Walbank, alleging that the chimney had been constructed in accordance with the plans and therefore that responsibility for defects should be with the architect. Mr. Walbank demurred to the action in warranty, contending that no such action lay in a case of this kind. Mr. Justice Davidson dismissed the demurrer. The Civil Code provides that if a building perish within 10 years, from a defect in its construction, the architect and the builder are jointly and severally responsible,

CHRIST CHURCH CATHEDRAL.

VERY few churches in Montreal are comparable from a constructional, as well as from an artistic point of view, to Christ Cathedral, of which I have attempted herein to give a short description. The great cost of stone found in this district, owing to its hardness and the difficulty experienced in carving it, tends no doubt to generalize the employ of lumber and galvanized iron, which has been so extensively used lately where stone should have been used for decoration and construction. This cathedral is an exception to the majority of our churches, having been built by the wealthiest congregation of the city; and nothing was spared to make it artistic and handsome. It is the only structure of its kind here, where stone has been so lavishly used for exterior as well as for interior effect. It is built on the north-west corner of Phillips Square, on the block bounded by Union avenue, University street and St. Catherine street, on a site that was donated by George III, King of England, for the erection of the cathedral which was destroyed by fire in 1856. Work was commenced on the existing church immediately after the fire, and was completed in 1859, when the edifice was opened for service. The plans were prepared by a prominent London architect, who unfortunately was not permitted to see this gothic chef-d'oeuvre carried out, but died before the foundations were out of the ground, at the beginning of the year 1857; when a successor had to be appointed to carry out his plans.

But two blunders were committed, one owing to the entire ignorance by the architect or his representative of the nature of the ground on which the church was to be erected, and the other to the severe climate of this country in winter. The first was due to the inefficiency of the spire foundation, which having sunk considerably before it got half way up, had to be taken down and rebuilt. The other blunder is practically irreparable, experience having shown that part of the stone employed in the construction cannot resist our severe winter frosts, and every year a goodly amount of money has to be laid aside for the replacing of the damaged stones. All the stone used in exterior trimmings and also in the interior, where there is a considerable amount of stone, was specially imported for the purpose from Caen, France. This stone resembles very much in appearance the Ohio standstone, and was very extensively used for inside work in England at the time the church was built; it is an exceptionally suitable material for executing fine sculpture and moldings—when not exposed to weather. Mr. Taylor, architect, was appointed some years ago to pay regular visits to the structure and attend to all restoration that the course of time might have rendered necessary; nothing is allowed to be touched or altered without professional advice, as it is considered that an inexperienced hand can destroy in an hour what it has taken years for an artist to produce.

A few years ago two stones fell from the spire through the roof, and the beautiful stone cross over the chancel gable also fell to ground, broken into atoms. The architect was sent for, and all the fragments were gathered and put together, and a reproduction of it made of the same material to replace the broken one. Several other ornaments and moldings also perished, but all were treated in the same manner. The only part that has not yet been affected by the frost is the window tracery—which are of stone—and great care is taken to preserve them intact. The chancel and aisle windows and the rose window in front have very remarkable tracery, and should they be injured it would be found extremely difficult to repair windows of such sizes. A curious thing to note is that nearly all the window tracery are of different design, such being the case with the row of circular windows over the main nave and on each side of it. The spire is built entirely of stone, and contains a beautiful clock and chimes. It is reputed to be the highest stone spire in Canada, measuring about 225 feet from the ground by — feet square at its base above the roof.

On Union avenue, close to the church, stands a handsome little monument, about 28 feet high, built of Ohio sandstone, in commemoration of Bishop Fulford, first bishop of Montreal. The front porch of the church is also very handsome, and fine details are to be found, such as crochets, gorgoils and elegant moldings.

Now let us glance at the interior, which is as interesting as the exterior. As we enter there is no flashy decoration, and anyone expecting to see fret or ginger bread work will be disappointed; but everything is so appropriate, neat, simple and artistic, that on closer inspection we are forced to admire the whole. The beautiful stained glass that adorns the chancel and aisles is mostly of Clayton & Bell's make, and of a Brussels firm. On the left hand side of the chancel is the organ, which is hardly apparent, and which is reputed not the most powerful, but the most perfect musical instrument of its kind in America, and is a reproduction of the old organ that was burned with the old cathedral in 1856. It was built by Hill & Son, of London, Eng., who had preserved the plan of the original organ.

The Ledilia (marked 1 on the plan) and baptismal font (5) being all stone, deserve more than a passing glance, and exhibit admirable carving. At (4) stands on a pedestal a bust of Bishop Fulford; in (2) is the Bishop's chair, and in (3) is his throne. The two rows of arcade dividing the aisles and nave, and door and window jambs, are all of solid stone, and the capitals of the columns each contain a specimen leaf of the different kinds of Canadian trees carved in the stone. The altar cloth, made by the Sisters of St. Margarets, of this city, the memorial window in the left transept and the fine brass chandeliers, are of recent date, and were executed from drawings by Mr. Andrew T. Taylor, F.R.I.B.A.

An interesting part of this church that should also receive some attention from the visitor, is the Chapter House over the vestry, where beautiful stone carved statues supporting the roof trusses can be seen. In a word this is a church thoroughly English in character, that is very seldom seen on this side of the Atlantic; and I would advise my professional brethren, when they have an opportunity, not to forget to pay a visit to what I consider one of the finest specimens of gothic architecture of the Decorated Period on this continent.

I desire to here thank publicly the Rev. J. G. Norton, M. A., D. D., rector of the Cathedral, and Mr. Andrew T. Taylor, F.R.I.B.A., architect in charge of the restoration of the church, for the valuable information which helped me in preparing the above.

P.

ESTIMATING.

MANY good workmen and thorough superintendents make poor attempts at estimating, and often their efforts in this direction prove their ruin. On the other hand, the writer has known poor or indifferent workmen who seemed to have a natural gift for arriving at the cost of proposed works; not by any proper or systematic course, but by a sort of intuition which stood them instead of actual trained knowledge. Men, however, of this sort, whose conclusions are jumped at, are not reliable in their figures, when the works estimated are above the average magnitude; and on more than one occasion I have known these haphazard contractors to have been sorely bitten when reaching out beyond their limits.

Estimating, like everything else resulting from human effort, can only be a certain success when directed by a thorough knowledge of the subject and painstaking labor. There is no royal road to estimating, and the man who attempts to jump at the cost of a proposed building, and takes the contract at his own figures in the face of intelligent competition, either does not get proper returns for his labor, or jerrys the work,—either dilemma proving ruinous in the end. The best contractors are men who have been trained to the service, and whose knowledge of every detail in building, the cost of every variety of supply and material, whose acquaintance with the producing capacity of workmen, is complete. Such men are found among the regularly employed "Clerks of the Works," so-called in the British Isles, and in some portions of Europe and America. These men are supposed to know, and generally do, all particulars concerning buildings of every style and grade, and estimates made by them always deserve respect.

In this country the architect is perhaps the best authority on the cost of a proposed building, though I must confess that some estimates made by professional men in this country often prove wide of the mark, their figures generally being too low. There is one department of estimating, however, wherein the architect's figures are generally correct, and that is in the quantities. These, when given by the architect, may be relied upon, and having these, the wide-awake contractor ought to be able to get at the cost of a building pretty close. I have often thought it a mistake that quantities are not attached to specifications in some way, and that intending contractors be taxed a small amount for the privilege of making use of the figures. Let it be understood, however, that I do not advocate the doing of this extra work by the architect, gratuitously. To take out the quantities of a building of any magnitude, entails a great deal of labor and time, and it would be but just that these should be paid for by the parties who receive the benefits, who, of course, are the contractors. The cost to each aspirant need not be much, while the benefits are manifold, inasmuch as the figures may be relied upon; there is much time and tiresome labor saved, and no item will be forgotten or overlooked. The architect might also give the cubic contents of the building, with the actual cost per foot of similar buildings—not that I approve of the "cubing method" for estimating, for I believe it to be very faulty; but it might be given as a sort of guide by which the estimator could see if he had made any serious mistakes.

In a future paper I will endeavor to show a method of estimating, suitable to the requirements of country builders.

A. Z. Z.

Collingwood, July 7th, 1894.

TRADE NOTES.

Mr. Alex. Bremner, of Montreal, dealer in contractors supplies, has issued an attractive wall hanger, giving, by means of illustrations and printed matter, information relating to his various lines of goods.

Referring to the opening of the Zion Evangelical church at Berlin, Ont., the daily news of that town on June 18th said: "The gas reflectors and fixtures were supplied by I. P. Frink of 551 Pearl street, New York. The lighting of the church is on a style most complete, and was put in under the supervision of Mr. E. C. Breithaupt. The lighting is so perfectly arranged that though the church will be as light as day, there are no lights near the pulpit, to dazzle the eyes of the congregation, the reflectors spreading a brilliant light over everything."

Dr. Grady, of Eastport, Me., in company of an expert, has recently made an inspection of the black granite deposits at Bocabec, N. B., with the view it is believed of investing therein.

ILLUSTRATIONS.

COMPETITIVE DESIGN FOR PROTESTANT ORPHAN ASYLUM, MONTREAL.—DAVID A. BROWN, ARCHITECT.

The design which we illustrate received third place in the competition. The reproduction is from a drawing by Mr. O. Tolhurst, of Montreal.

RESIDENCE OF MR. W. T. MCMULLEN, WOODSTOCK, ONT.—A. WHITE, ARCHITECT.

The face stone work is of Credit Valley brown stone, the cut stone of Ohio buff free stone, and the brickwork of first quality Beamsville red pressed bricks. The roof is covered with Rockland slates. All outside woodwork will be painted a cream color. The hall, staircase and principal rooms will be finished in quartered oak; the bedrooms in clear pine, natural state. The parlor, dining room and two bedrooms to have open fireplaces, with tiled hearth and facings.

ORILLIA TOWN HALL AND MARKET BUILDING.—GORDON & HELLIWELL, ARCHITECTS, TORONTO.

The building is constructed of brick with stone trimmings and basement, and a slate roof. The general dimensions are 60×106, the tower and staircases projecting beyond this.

The front portion of building on ground floor is utilized for town offices, including a council chamber 40×32, town clerk's room and a committee room. The rest of ground floor is devoted to the market, and contains eight butchers' stalls or shops and a general market room for vegetables, &c.

The basement under market is devoted to cellar accommodation for stalls and a public lavatory.

The cellar under council chamber is used for boiler and fuel room.

In the two circular towers at front are two wide staircases leading to public hall on first floor and to the gallery of same. In the square tower is a private stair to the stage and dressing rooms of public hall.

The auditorium of hall on 1st floor is 56×64 feet, and the stage platform recess in rear is 32×25 feet. On each side of stage are dressing and property rooms. Around three sides of hall is a gallery to seat about 270 persons. The main floor of auditorium will seat about 600 persons.

The internal finish in town office portion is hardwood and in the rest of building pine. The walls of market are brick and the ceiling wood. The ceiling of auditorium is an elliptical arch in plaster.

NEW LEGISLATIVE BUILDINGS, VICTORIA, B. C.—F. M. RATTENBURY, ARCHITECT.

SKETCHES FROM CHRIST CHURCH CATHEDRAL, MONTREAL.

PRACTICAL CARVING.

A FEW remarks on practical carving may not be amiss at the present time, writes John Keily, of Toronto. Some would-be critics say: Why not use your eye? And a carver who is seen to use a compass or plumb-bob is said to be a mechanical carver.

Now the eye cannot always be depended upon. It seems to be a prevailing fault in drawing a circular curve to make it a flat curve, and a flat curve nearer to a straight line. In the oft repeated egg and tongue moulding, which takes a good carver to make, and which is attempted by every tyro or stone cutter, the chamfer of the egg is invariably on the left side, leaving it full on the right. Its section is not a half circle but the section of a thumb moulding. I observed the same defect on a number of organ pipes carved behind a figure of music.

I once had to finish an oval shield after a boss carver, who used his eye when roughing it out. Taking a centre line and stepping the compass to the right and then to the left, I found the latter was narrower than the right side: the outline on the left side flat, the right bulbous. A fulness on the right side of spiral bands is also a common occurrence.

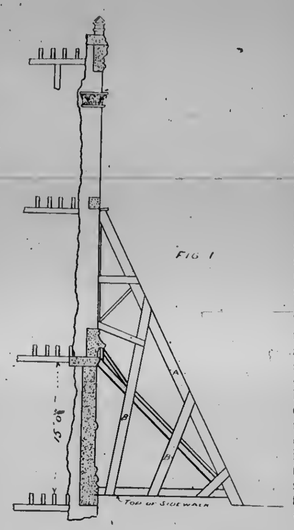
In carving a head or mask in stone there is a tendency to splay it off to the left and undercut it on the right. A proper carver when carving the capital of a column uses a plumb-bob on the bell of the cap to get the column line, carrying it well up to give the column vigor; whereas a novice will leave the bell projecting beyond the column line, and the foliage falling out from the astragal to the abacus.

Daloo, the great French sculptor, when modelling a figure from life, takes a number of fixed points in a mechanical way to determine the proportions of his subject, and then gets in his artistic work. Flaxman says "that Greek sculpture did not rise to excellence until anatomy, geometry and numbers had enabled the artist to determine his drawings, proportion, and motion; then and not before, a just expression might be infused in the truth and the harmony of parts, and the artist endow his statue with life, action and sentiment."

The town of Iberville, Que., has granted a bonus of $600 per year for ten years to Mr. H. Black, for the establishment of a factory for the manufacture of porcelain sinks and baths. Mr. Dakin will be the manager of the new concern.

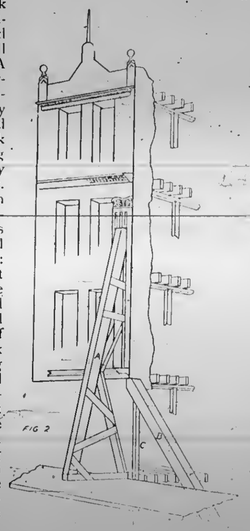
SHORING.

BELOW we show cuts of two examples of shoring which are in use on prominent streets in Toronto. In both these cases side walls are removed down to the footings about 14 feet below the sidewalk. In Figs. 1 and 2 the principal timbers A are built up of 3 pieces each to a thickness of 7½"×12", and in Fig. 2 the piece marked B is built up of 3 thicknesses of 4"×12". This timber is footed at the bottom of the new basement excavation 15 feet below the sidewalk. In Fig. 2 the shop front is entirely removed on the ground floor, and the corner shored up is supported by the post C, and also by another heavier upright which is omitted from the sketch to make the shoring clearer. The tie pieces are of 2" stuff spiked on both sides of the timbering. The differences in these two examples are mainly in the spread of the lower end of shorings, which is 15 feet in Fig. 1 and 6 feet in Fig. 2, and the way the braces are cut around the cornice in Fig 2. In both figures the height of shoring is about 30 feet above the sidewalk.



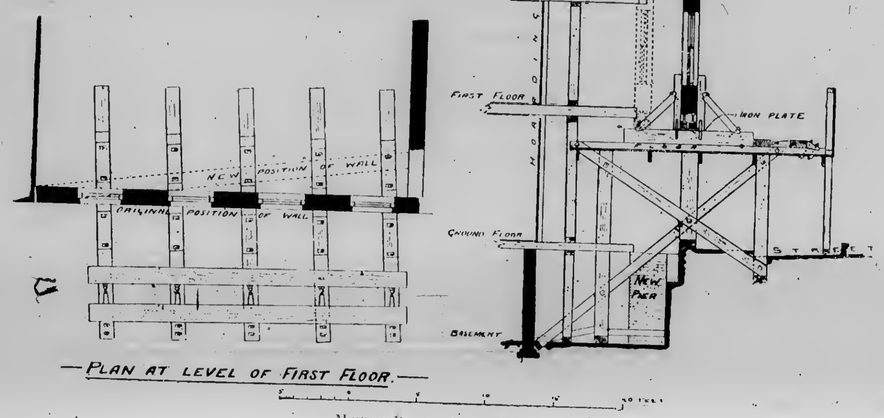
In this connection we reprint from the Building News the following interesting description and illustration of the methods employed in moving back a brick wall:—

In connection with the widening of Minster street, Reading, it has been necessary to throw a portion of the site occupied by Messrs. Watson Brothers' glass and china warehouse into the street. As Mr. Watson was very anxious that there should be no loss of time, and desired that any new front to his shop which might be erected should be similar to the existing one, the Borough engineer (Mr. Arthur E. Collins, Assoc. M.I.C.E.), designed and carried out an arrangement by which the existing front has been pushed back to the desired position. Notwithstanding that a good many persons, who well illustrate the saying that "A little knowledge is a dangerous thing," thought the intended operation a very dangerous one, as an actual matter of fact no more risk was incurred than during the progress of any ordinary constructional operations. Every necessary precaution was taken to avoid accident, and these precautions proved effectual. The actual operations were as follows:—The plate glass shop-front and the window sashes were removed; the floors and roofs were shored up and cut back to the extent of the intended setting-back of the front wall; five strong trestles were constructed beneath and across the girder supporting the front wall, and sliding pieces were placed on these trestles. The sliding surfaces having been well lubricated with soft soap and tallow, the weight of the wall was transferred to the sliding pieces by driving oak wedges between those pieces and the girder supporting the wall. The front wall was then cut away from the surrounding walls and from its supporting brickwork and columns. Screw jacks were then applied to the slides, and the wall was pushed back into its new position. To prevent the wall from falling forward into the street, should it show a tendency to do so, four sets of Tangye's differential chain blocks were attached to the wall and to suitable points in the building, these chains being kept just taut. To prevent any falling inwards of the walls, struts, consisting of stout scaffold poles, were butted on suitable parts of the building. These struts were constantly shortened as the wall moved back, so that whilst never touching the wall, at no time was there a greater distance than 1 in. between the moving wall and the end of the strut. The actual moving was performed in about two hours and a half, under the immediate direction of the borough engineer. Mr. George Lewis, of Castle street, the contractor, assisted by his foreman, Mr. William Church, executed the necessary work most ably, and business was carried on as usual throughout its progress. Messrs. Watson's premises in Minster street are three stories high, and have a basement. The wall moved was 30 feet long, 23ft. high above the first floor, and 18in. thick, including plastering, &c. The front is stuccoed. The east end of the front was moved back 3ft. 6in.; but the west end was not moved, as it was already fair with the adjoining building. The weight of the wall is about 38 tons.



COLOUR IN BUILDING.

AT a recent meeting of the Edinburgh Architectural Association, Mr. A. N. Paterson, M.A., read a paper entitled, "Colour as a Means of Architectural Expression." By way of introduction it was shown that the materials which the architect employs having each their colour value, his art is essentially chromatic, and that in consequence the study of colour is of the first importance; that, nevertheless, it has been much neglected by architects, and that to this among other causes is due much of the monotony of present-day architecture. Architectural expression s regarded to be as much a matter of color as of form, the term expression being used to indicate the individuality which differentiates one building from another, as well as the quality and character of the design in any one building. Three main lines of colour-study are laid down as being of most advantage to the architect. I. An examination of some of the principal laws of the science of chromatics, with the facts thereby to be discovered regarding the effect of colours according to their position and juxtaposition; a knowledge of these facts by itself will never produce fine results artistically, but they may be used by the artist as safe guides for the direction of the studies. The difference between light and pigments in relation to color is noted, and the laws regarding complementaries, contrast and small interval are explained and commented upon. The propositions regarding the use of color laid down by the late Owen Jones in his "Grammar of Ornament" are examined with relation to past examples of architecture and analogy from nature. II. Attention is turned, secondly, to the color qualities of our materials and the range of materials we have at our disposal, and it is found that there is no color which has not its exponent in almost every material the architect makes use of. The various materials are passed in review, with reference to their effect from a color point of view; stones, marble, of which it is thought more extended use might be made over small surfaces in external work; cement used as granolithic, rough cast and (as a form of small decoration) sgraffito; the various woods, singly and in combination, with a remark as to the greater use of inlays; bricks, tiles and terra-cotta; the metals, mosaic and other forms of internal and external decoration. With regard to these last, the more extended collaboration of artist craftsmen is pleaded for as the only means of producing the finest results. III. In the third place, attention is directed to the use of color in the architecture of the past. It is found that color has always played an important part, and a rapid survey is made of pre-classic days, of Greek and Roman, Romanesque and Byzantine, Mauresque, Gothic and Renaissance architecture, with a more careful examination of some Italian temples illustrated—St. Mark's at Venice, with the Ca d'Oro and other palaces there, the churches of Sienna and Florence and the houses of Bologna and Perugia. The use of colored materials and pigments in England and Scotland in past times is inquired into and illustrated. In conclusion, the tendency towards a more widespread use of color in the present day is noted and welcomed, and particular reference is made to buildings in Edinburgh and Glasgow giving evidence of this. The counter influence of fog and smoke is discounted, as much of an architect's work lies in the country beyond their reach, while it is further contended that even if a colour effect in towns is limited to a few years' duration it is none the less worth being carried out, for that beauty is none the less beautiful because it is transient.



MOVING BACK A BRICK WALL.

THE NEW UNION DEPOT, TORONTO.

THE erection of the new union depot at Toronto is proceeding satisfactorily. The entrance to the passenger waiting rooms on Front street is spanned by an immense arch, the dimensions of which are: span, 44 feet; rise, 28 feet; thickness, 4 feet; depth of voussoirs, 6 feet. There is also an inner arch, of the following dimensions: span, 54 feet; rise, 32 feet; width, 12 feet. The outer arch is believed to be the largest, forming part of the construction of a building, to be seen in America. The existence of two towers, one on each side, has rendered it possible to make this arch such an important feature of the building. It is built of Credit Valley brown sandstone, the inner arch being constructed of imported Scotch sandstone, which is also to be employed to a considerable extent for the interior walls of the waiting room. The progress of the work has been considerably delayed by the difficulty experienced in getting the necessary supply of this stone at the time required. The contractor for the masonry of the building, Mr. Benjamin Gibson, of Oshawa, Ont., is deserving of praise for the excellent character of his work. It is one of the finest specimens of masonry construction to be seen in Canada.

Black granite polishing works are being erected at Bocabec, N. B.

Mr. Wade, the well-known English sculptor, has been commissioned to erect the statue of Sir John Macdonald in Kingston.

A company is being incorporated at Pictou, N.S., under the name of the Cairo Polish Co., to manufacture bricks, tiles, pipes, paints, etc. Capital $10,000.

The Sydenham Glass Company, of Wallaceburg, Ont., are applying for incorporation, with a capital stock of $50,000, and will erect a factory at Wallaceburg to manufacture glassware. Mr. A. G. Baird, is acting secretary.

NEW PLUMBING BY-LAW OF THE CITY OF MONTREAL.

FOLLOWING are the provisions of the by-law for the regulation of plumbing, drainage and ventilation adopted by the Council of the City of Montreal on June 24th, ult.:—

Sec. 1. Every master plumber, or drain builder or drain layer shall be required to register his name and place of business at the office of the board of health, and to give notice at the said office in case of the removal of his place of business.

Sec. 2. An official list of such plumbers and drain builders or drain layers recognized by the Board of Health, shall be published once a year during the month of May.

Sec. 3. It shall be unlawful for any person to carry on the trade of plumbing or drain making in the city of Montreal, unless enregistered as above.

Sec. 4. All plumbing and house drainage and ventilation in the city shall be made and constructed in accordance with the following rules, which shall be binding on all parties concerned :

(1)—No drain or plumbing work or drain ventilating shall hereafter be made in any new building unless plans, drawings and a description of the same shall have been previously submitted by the proprietor, or his representative, in the health office, at least eight days before the commencement of the work, and unless such plans and drawings shall have been approved of and authorized by the sanitary engineer ; and in case of repairs or alterations affected by sanitary regulations, notice shall be given to the health department at once ;

(2)—No part of the work shall be covered or concealed in any way until after it has been examined and approved of by the sanitary engineer or his representative ; and notice shall be given to the health department when the work is sufficiently advanced for such inspection ;

(3)—The water department shall refuse to turn on the water unless the demand for the same is accompanied by a certificate of the sanitary engineer, to the effect that the works have been inspected, and found to be in accordance with the said rules ;

(4)—The material used shall be of good quality and free from defects, and the work shall be executed in a thorough and workmanlike manner ;

(5)—The arrangement of the soil, waste and ventilation pipes shall be as perpendicular as possible ;

(6)—The soil, drain, waste and drain ventilation pipes shall be at all times exposed to view ready for inspection and for convenience in repairing ;

(7)—When necessarily placed within partitions or recesses of walls, soil, drain, waste or ventilation pipes shall be covered with woodwork, so fastened with hinges or round headed screws, as to be readily uncovered ;

(9)—Every house or building shall be separately and independently connected with the street sewer, in front of such house or building, or with such other sewer as shall be designated by the board of health ; but in all cases of dwelling houses, there shall be a special communication with the street sewer for each fifty feet frontage of said houses if there be only four dwellings in the said space ; and in case there shall be more than four dwellings in the said space of fifty feet, the special communication with the street sewer shall be as directed by the board of health ;

(10)—Every such drain put in and covered without due notice to the health department shall be uncovered within 24 hours for inspection by the sanitary engineer or his representative ;

(11)—No brick, sheet metal, earthenware or chimney flue shall be used as a sewer-ventilator, or to ventilate any trap, drain, soil or waste pipe ;

(12)—Soil pipes shall be of cast or wrought iron of the weight specified in subsection 20, and shall extend at least two feet above the highest part of the roof, or coping, light, shaft louvres window or other opening ; they shall be of the same size throughout, and in no case shall they be less than four inches in diameter ;

(13)—Soil, waste and vent pipes in an extension, shall be carried above the roof of the main building when they are closer than twenty feet to the windows of the main building of adjoining houses ;

(14)—All water closet traps must be amply back air ventilated with a pipe from 2" to 4" or other approved device to prevent syphoning ;"

(15)—Joints of sewers and soil pipes shall be gas and water tight ;

(16)—When stacks of pipe are required for sinks only, they shall be carried full size through the roof and be not less than 2" for 4 sinks or 3" for over that number ;

(17)—When lead pipes are used to connect fixtures with vertical soil or waste pipes, or to connect traps with vertical vent pipes, they shall not be lighter than six lbs. sheet lead to the square foot ;

(18)—There shall be no traps in connection with vertical soil or waste pipes unless a permit so to do shall be obtained from the board of health ;

(19)—All pipes shall be sound and free from holes or cracks ;

(20)—The following weight per lineal foot or yard shall be accepted as standard :

IRON PIPES.

For plumbing work.

2 inch,	4	pounds per lineal foot.		
3	"	6½	"	"
4	"	9	"	"
5	"	12½	"	"
6	"	17	"	"

For drain work.

4 inch,	13½	pounds per lineal foot.		
5	"	17	"	"
6	"	20	"	"

LEAD PIPES.

1½ inch,	1½	pounds per lineal foot.		
1½	"	2	"	"
2	"	2½	"	"
2½	"	4½	"	"
3	"	5½	"	"
4	"	7	"	"

For waste sink pipes.

2 inch,	10	pounds per lineal yard.		
3	"	15	"	"

Lead waste pipes, bends or cesspools shall be equal to not less than 6 lbs. per square foot of sheet lead ;

(21)—The fittings used in connection with said pipes shall correspond with them in weight and quality ;

(22)—The plumbing work shall be tested by the sanitary engineer or representative, or an officer authorized by him, in presence of the plumber, (when the latter is required to be present) with the peppermint, smoke, or air ;

(23)—When defective pipes are discovered, they, shall be removed and replaced by sound pipes ; defective joints shall be made tight and every part of the work in which defects are found shall be made to conform to the present rules ;

(24)—Joints in iron drain, soil and waste pipes, shall be so filled with oakum and lead and hand caulked so as to make them gas tight, and they shall not be painted, varnished, tarred or puttied over until after inspection, unless the sanitary engineer does not signify his approval or disapproval of the work within 36 hours after the health department shall have been notified that the work is ready for inspection ; the said joints may also be screw joints ; should the work prove to be satisfactorily executed in the judgment of the sanitary engineer, he shall grant a certificate to that effect to the person concerned ;

(25)—All connections of lead with iron pipes shall be made with a brass or copper sleeve or ferrule of the same size as lead pipes, put in the hub of the branch of the iron pipe and caulked with lead ; and the lead pipe shall be attached to the ferrule by a wiped or overcast joint ;

(26)—All connections of lead pipes, shall, where practicable, be by wiped joints ;

(27)—No tile shall be connected with the waste pipe unless the same be provided with a flange to admit of a proper connection being made ;

(28)—Every water-closet, urinal, sink, basin, wash tray, bath, and every tub shall be separately and effectively trapped. This rule shall apply to a set of tubs, but only one trap shall be required for the set ;

(29)—The connections between iron and tile pipes shall be made with the best Portland or Roman cement or by other means approved by the board of health ;

(30)—Traps shall be placed as near the fixtures as practicable, and in no case shall they be distant more than two feet from the fixtures ;

(31)—There shall be only one trap under the water-closet and that immediately beneath the same ;

(32)—All waste pipe fixtures other than water-closets shall be provided at the inlet of such fixtures with strong metallic strainers to exclude from such waste pipes all substances likely to obstruct them ;

(33)—In no case shall the waste pipe from a bath, tub or other fixture be connected with a water-closet trap ;

(34)—Overflow pipes from fixtures shall in every case be connected with the inlet side of the trap, and above the water ;

(35)—Drip or overflow pipes from the safety pan under water-closets and other fixtures, or refrigerators, or from tanks, other than those of water-closets, shall be made to run into some place in open sight ; and in no case shall any such pipe be connected directly with the drain, waste or soil pipe ;

(36)—Water-closet apartments shall open to the outer air, by means of a window, shaft or air duct, going through the roof, or by vent shaft to the chimney ;

(37)—Every water-closet shall have a cistern supply, and in no case be supplied directly from the city reservoir supply pipes ;

(38)—In houses containing one or more than one family, there shall be one water-closet for each family, and a separate cistern for each closet ; in other buildings, however, a group of closets may be supplied from one tank, but not water-closets on different floors ; and at least one water-closet to every 15 inmates ;

(39)—The overflow pipes from water-closet cisterns shall discharge into an open sink, or the basin of the water-closet, or where its discharge will attract attention and indicate whether waste of water is occurring, but not into the soil or waste pipe or into the drain direct ;

(40)—Valves must be so fitted and and adjusted as to prevent wasting of water ;

(41)—No privy vault or cesspool for sewage shall be permitted in any part of the city where water-closets can be connected with a public sewer in the street ; when no sewer exists in the street a permit for a temporary privy may be granted by the board of health ; and in such case it shall be water tight, of a capacity of 15 cubic feet ; the sides and bottom shall be constructed of cemented brick twelve inches in thickness and well cemented inside with hydraulic cement ; such vault may be constructed of cast iron, the shape or form of which shall be either circular or oblong without angles, and with a concave bottom ; it shall be provided with a ventilation pipe at least 4 inches in diameter, extending from the pit through the roof sufficiently high as to prevent inconvenience to occupants of neighboring houses ; the seats shall have a tight fitting cover ; it shall have an aperture opening exteriorly to allow of cleaning by pneumatic process, such aperture to be 2 feet by 1½ feet in size ; or else the flooring shall be air tight and shall have a tightly fitting trap door communicating with the pit ; the top of the vault shall be one foot above the level of the ground ; nothing shall be put into the pit, excepting human excreta ; privies shall be located at a distance of 20 feet (or more according as the board of health may deem necessary) from any house or street ; they shall be emptied when the contents reach to within eighteen inches of the top of the vault, by persons appointed by the board ; no offensive smell or gases may be allowed to escape therefrom. But, in no case shall a privy be allowed within the walls of a dwelling house or in any property situated on a street having a sewer ;

(42)—No steam exhaust, blow off pipe shall connect with a sewer di ectly or any house drain, soil pipe or waste pipe ; such pipe must first discharge into a tank or condenser ;

(43)—Cellars shall not be connected with the house drain unless absolutely necessary, and by special permission of the board of health, and according to plans approved of by the board ;

(44)—A sub soil drain shall be provided when absolutely necessary, and shall be constructed and trapped to the satisfaction of the board of health ;

(45)—No trap shall be permitted between the house drain and the public sewer, unless by permission of the board of health ; conditionally however that such trap shall have a hand hole for cleaning purposes and a fresh air inlet pipe, the whole as may be decided upon by the board of health ;

(46)—Drains in yards shall, in all cases, be trapped below frost, that is to say : four feet at least under ground ;

(47)—In the case of privy vaults now drained into a common sewer, they shall be isolated by means of suitable traps placed below frost and according to instructions from the board of health ;

(48)—In the case of a new house being built or one already existing being repaired, wherever there is a public sewer in the street, a water-closet shall be put in, to the exclusion of privy pits ;

(49)—The inspection of drains within the line of street shall be under the exclusive control of the board of health ;

(50)—Gas pipes will be tested in the presence of the sanitary engineer or his representative ;

(51)—Gas companies are obliged to place a stop cock to every main pipe ;—

Sec. 5. The word "board" wherever it occurs in this by-law, means the board of health of the city of Montreal ; and the word "sanitary engineer" means the sanitary engineer appointed by the council to carry out the provisions of this by law, or his representative.

Sec. 6. Any person contravening any of the provisions of this by-law shall be liable to a fine, and in default of immediate payment of the said fine, and costs, to an imprisonment—the amount of said fine, and the term of said imprisonment to be determined by the recorder's court, *at its discretion ;* but the said fine shall not exceed forty dollars, and the term of imprisonment shall not exceed two calender months ; the said imprisonment, however, to cease at any time before the expiration of the period fixed upon by the recorder's court, on payment of said fine and costs ; and where the infraction is continuous, such infraction during each day, shall constitute a separate offence.

THE DIFFERENCE IN AMOUNT OF RADIATION REQUIRED IN BUILDINGS OF GOOD AND POOR CONSTRUCTION.*

To illustrate the subject before us I will recite my experience in several buildings. In the fall of 1879 I placed a low pressure steam heating apparatus in a building designed for a home for old ladies. Many of the rooms were small, and in order to warm them without question a radiator was placed in each room. Knowing that a high temperature would be agreeable, the calculation was made that one foot of radiation would warm 40 cubic feet of air. This we considered very liberal when the fact that we used the Gold sheet iron radiator is taken into account. We were, however, doomed to a very serious disappointment, as the temperature in the rooms on the windward side of the house frequently fell to 50 degrees, and sometimes even below, during severe cold and windy weather. After reconsidering all the conditions we determined to add a large percentage of radiation, which was done, and the building has been thoroughly warm ever since. The amount of radiation added in many of the exposed rooms was from 50 to 100 per cent. over that originally supplied. To my mind the rooms in this building are very uncomfortable, for the excessive amount of radiation required to maintain the temperature produces a very disagreeable condition of affairs, together with the excessive loss of heat through the thin walls and many air leaks. It was soon found that although the ratio of radiation was very excessive under the existing conditions the condensation was very rapid, and more boiler power was required to maintain the steam pressure. Consequently an additional boiler was supplied, at the expense of the heating contractor, which gave plenty of generating power, but all this was accomplished at a heavy proportional loss to the contractor. To my mind as I review the entire matter I find that the original calculation for the boiler and radiating surface were correct providing the building in question had been ordinarily well constructed. But from subsequent surveys I conclude that the architect and building contractor produced about as poor a specimen as it was possible to do and have it stand up as a public building. The result is that the amount of fuel needed to warm the building is enormous.

I have in my mind another building which belongs to one of our popular colleges. The building was constructed in 1872. The location was on the brow of the hill where the front was exposed to the force of the northwest winds. It was the intention of the heating contractor to make this building very warm, and all calculations were made with this object in view. After the apparatus was complete and the weather became cold it was found that many of the small rooms in the west front did not warm to the required temperature, and an investigation was made to determine the cause if possible. We referred to our calculations as to boiler, piping, radiating surface, etc., and found that the apparatus was constructed according to our calculations; nevertheless we were confronted with a number of cold rooms. We finally determined that the only way to satisfy ourselves was to live in the building and keep a record of the temperature, both in the rooms and outside. While this was in progress I visited the building one very windy day and in entering some of the west rooms I was surprised to find that the hall door would be pulled away from me and shut with a report like a gun.

I supposed at first that the windows were open, but examination showed that they were closed as tight as possible considering their construction, but the air was constantly driven through the brick walls of the building, in fact, the volume of air forced into the room was so great that the hall door was opened with difficulty. The radiators in these rooms were liberally increased and the warming of the building has been very satisfactory to its occupants. The heating contractor in this case did not meet with a decided loss, as a very liberal allowance for the exposure of the building had been made in the original calculations.

Another striking case comes prominently before me. About eight years since I placed the heating in one of our State normal schools. The building was in a very exposed location and the radiating surfaces were very carefully apportioned in order to fully meet all conditions. One large class room, containing about 100,000 cubic feet, was provided with one square foot of radiation to 40 cubic feet of space. This was thought to be excessive at the time but we wished to do the work right the first time and not have any alterations or additions to follow the work, so the full amount of radiation was supplied. When the weather became severe this room was very cold and radiating surface was added at various times until the ratio was brought up to 1 to 18 and the desired temperature secured. The larger part of the radiation was direct, in fact, all radiation which was added was direct. I found that while standing in the room during a severe northwest wind, you could feel the wind on your face as it came through the wall of the building. In the illustrations cited the buildings were very carelessly constructed, the architects in charge giving very little attention to the minor details which have the most important bearing in the comfortable use of the building.

I will now call your attention to the reverse of the conditions named above. Last year I contracted to place a small hot water apparatus in an old residence which was being altered slightly and converted into a small apartment house. The building was not badly exposed, so the calculations where based on a moderate amount of radiating surface. The apparatus was complete in the fall and the tenants moved in. The fire had not been started but a few days when there was a general complaint of too much heat, especially in the bedrooms. I find that the latter contain about 1,500 cubic feet and a radiator of 32 square feet was used to supply the heat. Our advice was to shut the valve in the radiator and run the water at a lower temperature, and when very cold weather came they would be very happy with nicely warmed rooms. Our suggestions were partly followed, but the complaints of over heating were almost constant and after passing partly through the winter both owner and tenants demanded that the radiators be removed from all the bedrooms at least. This was done and there remained in these rooms a riser of 1¼ pipe, which contains about four and a half square feet of radiation surface. In a room of 1,500 cubic feet, or a ratio of 1 to 333. The bedrooms being outside rooms, I have never had the opportunity to examine this house but there is no doubt as to its good construction. I might further say that I am advised that the temperature of the water is kept down to 140 to 160 degrees in the coldest weather.

* Paper read by Mr. E. P. Bates before the Sixth Annual Convention of the Master Steam and Hot Water Fitters' Association of the United States, June 19, 1894.

A few years since I built a small stable. Its dimensions are 24 by 36 feet on the ground. The ground room is used as a carriage room, horse stalls, harness room, etc. In practice the floor is commonly used as one room; above is a hay loft, with a room for the driver over the harness room. To my mind it is desirable to keep the stable moderately warm through the winter and to accomplish this with a moderate outlay in apparatus and fuel. Over the horse stall is a ventilating pipe running through the roof, this pipe is 12 inches in diameter and is always open summer and winter. Usually the air is going through it at a high velocity. There is no special provision to bring air into the stable, but the doors and windows are ordinarily well fitted, and there are large leaks about the entrance to the carriage room which has a sliding door about 9 feet square and opens to the north. In using the stable no difficulty was found to warm it to 60 degrees in the most severe weather, and an ordinary globe stove was used with a grate 8 inches in diameter. The amount of fuel used per season is between three and four tons. The stove pipe passes through the driver's room and heat given out by the pipe maintains a comfortable temperature in that room. I believe this stable is more comfortable in summer and winter than the average stable, although many of them may be much more expensive in construction. The stable is built of wood. The frame is balloon style, the upright stands are 2 by 4 inches, set about 16 inches between centers. On the outside of these studs I placed a course of rosin-sized building paper and one thickness of coved siding. In order to prevent the buckling of the paper at the laps, and to prevent a rapid change or circulation of air between the studs, I placed a 2 by 4 inch girth lengthwise (between the upright studs) on the sill; then, once in three feet, cut in a 2 by 4 inch as an additional girth. The paper being a yard wide abutted on this extra girth which held the edges tight and prevented the circulation of air from cellar to hay loft, and *vice versa*. On the inside of the carriage rooms on the ground floor, as well as other rooms on the ground floor, a course of building paper was used and ceiled over with ½-inch narrow Canada pine for a finish. Under the roof of the hay loft was laid a course of building paper also on the ceiling of carriage room before the ½-inch wood ceiling was laid. At the top of carriage room where the studs and joist join, I stopped off with boards to prevent the circulation of air. The idea of using the cross girths once in three feet and building paper on the inside of the walls was very amusing to the old carpenters employed on the work, but it is very satisfactory in a cold day and equally so in hot weather, the building being much more comfortable than many dwellings which are built at a much greater cost per cubic foot. It will be noticed that the stable here described is of very inexpensive construction and would be very cold in winter and hot in summer except for the succession of dead air spaces in the walls, cove siding being one of the poorest materials for keeping the wind from penetrating a building. Believing that I was correct in theory I determined to carry out my ideas more carefully in the construction of a house two years since. This house to which I will refer stands alone fully exposed on all sides on high ground, in Syracuse, where the temperature frequently falls below zero, and occasionally 15 to 20 degrees below zero.

It is constructed of wood and is comparatively inexpensive. The frame is what is known as balo on with slight modifications. On the outside of the frame are placed hemlock boards planed on one side, and over the hemlock is placed a course of heavy building paper, care being taken to leave no bare spaces, or uncovered knot holes; also that the paper fitted properly around all corners, windows and door frames. A 2 by 4 was nailed to the sill to prevent the air from cellar going to the attic or *vice versa*. Once in three feet a cross girth 2 by 4 inches was cut in between the upright studs to make a dead air space in the walls. This was also done in the partitions. At the ceiling of each story, a board to fill the space between the joists were inserted : said boards were covered with building paper. Over the partitions in the center of the house a stop off was inserted in a similar manner to prevent the air from passing from side to side of the house and cooling the ceilings of the various rooms. The roof boards were covered with paper before the shingles were laid. Every point was carefully looked after to prevent air leaks, the object being to get dead air spaces in all the walls as far as possible to do this. The next point was to install a good warming apparatus, and after having the old saw about the shoemakers' wives and blacksmiths' horses handed to me several times, I determined to erect a heating apparatus which would surely warm the house every day. I therefore placed in the house a No. 6 Bates's self feeding boiler containing 103 square feet of fire surface. This boiler is brick set. Allow me to speak of a peculiarity of this boiler, quite different from many which are advertised. It does not save any coal. They will burn all you fire into them, but if the firing is done with any reason the boiler will give you an equivalent in heat for every pound of fuel it consumes. The house in question being three stories it was decided to make a combination apparatus, i. e., hot water and steam, using hot water stacks for the five principal rooms, and steam radiators for bath, back hall and the small bedrooms. The hot water was circulated from the water line, the boiler set in the usual way for carrying steam, with automatic water feeder, automatic draft door, etc. I placed in the house, which contains about 16,000 cubic feet of air space, 452 square feet of radiation, equal to one square foot to 33 cubic feet of space to be warmed. Of the above 350 square feet was in the indirect hot water stacks and 127 square feet distributed in seven small radiators. For ventilation I built one chimney stack which connects conveniently to most of the rooms. In this chimney stack I placed eight tile flues made of vitrified pipe without hubs and all eight inches in diameter except the flue for the fire place in dining room which is to inches in diameter. These fires are used as follows: one for steam boiler, one for laundry stove, one to ventilate laundry (being three in basement), one for fire place, one for range, and one for hood over range to take off heat and vapor from cooking (being three on ground floor). On the second floor there is one flue from the large bedroom at the base of which is set a Franklin stove, and the other and eighth flue in the back hall. The bedroom being several feet from the chimney has a separate flue of tin and galvanized iron extending through the roof independently, with a globe ventilator on top. Every test made shows each flue carrying out large amount of air, and those flues to which fires are connected are very satisfactory ; in fact, they never fail to draw, and the course or velocity of the wind seems to make no difference, so it is evident that a rapid change of air is going on constantly.

As to results. When the thermometer registered 5 degrees below zero during the past winter we used one stack of pin radiators in the reception hall. Said stack contains eight sections. The register over the other stacks was kept closed, a radiator of 16 square feet in back hall of second floor was filled with steam, and a radiator of 18 feet on third floor was partly filled, equal to ten square feet, or in all 108 square feet in active operation in severe weather. There is no doubt we receive some benefit from the stacks where the registers were closed as there is a small percentage of leakage through the registers, and some heat given off by the tin flues running to the upper rooms. If only 108 feet were used the ratio would be 1 to 135. After having several cold days and demonstrating the fact that the amount of radiation was greatly in excess of the amount which could possibly be used, radiators were removed from the house, to the amount of 86 feet of direct radiation and 60 feet of indirect, the latter being the stack placed to warm the drawing room and was not used, as the room was thoroughly

warmed by the hall stack. It was found also that during the coldest days and evenings it was comfortable to sit in any part of the house, even the rooms where the registers were closed, also that the difference in temperature between the outside and partition walls was slight. One fact worth meationing is that the bath room was in constant use, and that it was designed to heat it by means of a brass coil nickel plated containing twenty feet of one inch pipe, but the valve was not opened during the winter the room being comfortable at all times to take a bath. During this season it is my intention to extend the tin flues to three bedrooms from which the direct radiators have been removed, as the stacks are abundantly large to supply them with heat. I might say in explanation that I should not have carried heat enough to carry steam, but for the fact that one of the upper rooms was used as a sewing room and steam was required to reach that room. In my opinion I shall not need to carry the water above 180 degrees the coming winter to perfectly warm the entire house. Under the conditions here described the boiler ran with the minimum of care, the draft door remaining consequently closed days at a time, the grate was shaken once in twenty-four hours in the most severe weather, and only once in 72 hours in very mild weather. With a temperature of 32 degrees outside, water at a temperature of 110 degrees to 120 degrees at the boiler was sufficient.

The question may now be asked what has all this matter of construction to do with our craft? We do not build houses or other buildings; we must take them as we find them, good, bad, and indifferent, and place in them a heater that will fill our guarantee, be it more or less. This is a fact from one standpoint. There is, however, another view to take of the subject; every trade is responsible for existing conditions to a certain extent; by agitating a subject we bring about reforms, and if fifteen to forty dollars judiciously expended in the construction of a small residence will save the full amount in the value of fuel in one or two seasons and add largely to the comfort of the occupants all the time, our efforts are well expended in diffusing the knowledge of the fact, and intelligent inquiry will be well rewarded in its research. Further, we all make our great successes in well constructed buildings and our failures and sometimes losses in those of poor construction. With this in view I hold that it is largely to the interest of the steam fitter and heating engineer to promote in every way possible the desire which the owner and architect may have for a well constructed building. "Continual dropping wears the stone."

PERSONAL.

Mr. Surtees, City Engineer, of Ottawa, is at present on a visit to New Brunswick.

Mr. Fred. Batty, manager of the stone quarries at Wallace, N. B., died suddenly of heart disease a few days ago.

Mr. Edward Copping, City Building inspector for Toronto, received severe injuries a few days ago, by being thrown from his buggy.

Mr. Eustace G. Bird, who has been pursuing the study of architecture in England and on the continent for several years past, has returned to Toronto.

Messrs. Strickland & Symons, architects, have recently removed their offices from Toronto street to Aberdeen Chambers, corner of Adelaide and Victoria streets, Toronto.

Mr. D. Norman MacVicar, late of Messrs. Taylor & Gordon's office, Montreal, has associated himself with Mr. David R. Brown, architect, under the name of Brown & MacVicar.

Mr. Richard Dinnis, senior member of the firm of R. Dinnis & Son, contractors, has recently returned home from a visit to Great Britain. He describes business conditions in England as discouraging in the extreme.

PUBLICATIONS.

The July Cosmopolitan marks the close of the first year since the revolutionary announcement was made that the price of that magazine, already low had been cut to one-half of three dollars a year. Even severe critics admit that with each succeeding number there has been a betterment in the quality of articles and illustrations, and the size has remained unchanged.

Mr. Charles Baillairgé, of Quebec, at the last meeting of the Royal Society at Ottawa made an interesting contribution to the at present popular subject of Technical Education, in a paper entitled "Technical Education of The People in Untechnical Language." Mr. Baillairge holds that the education of the masses should not go beyond the three R's and object lessons in scientific subjects. "Let us beware," he says, "of too much education; there is a danger of over doing the thing, and thus causing our should be agriculturists to become dissatisfied with their parents mode of livelihood, flocking towards populated centers, there to become second and third class professionals of every hue, with little or nothing to do; with mischief and discontent and anarchical tendencies following in the wake." To our way of thinking the need of the times is in the direction of a change in character and methods of instruction rather than in restricting education.

RECENT CANADIAN PATENTS.

Mr. George A. Watson, of Toronto, has secured a patent, No. 45,906 on a sectional hot water heating boiler.

Messrs. William Pinkerton and Joseph Barrett, of Toronto, have been granted a patent on a building composition consisting of about equal parts of limestone and stone or shale containing oxide of iron and silica melted and moulded into a homogeneous mass.

TO MAKE TRACING PAPER.—Home-made tracing paper is much less expensive than that purchased at shops. Common tissue paper can be had at something less than ½d. per sheet of the ordinary size, when purchased in quantities. To prepare it, mix a proportion of one of boiled linseed oil to five of turpentine in a cup. Put a single sheet of paper at a time on an inverted tea-tray, large enough to allow at least the half of the sheet to lie flat. The mixture should then be put on with a small sponge, one coating only, and that not too thickly; each sheet after such process should be hung over a string stretched across the room, and when all the clear oily marks entirely disappear, it will be ready for use.—Carpenter and Builder.

Dear Sir:—

With reference to our adv^t in your paper, we beg to state that it has proved of most excellent service to us. We have received numerous enquiries & orders from all parts of the Dominion, which we attribute to this adv^t, & which we would otherwise never have heard of.

Yours faithfully
Dominion Ornamental Iron Co

MEASURING MASONRY.

There are two widely different methods of measuring and estimating the value of masonry, to which we will find it necessary to attend. By the first of these methods the value of the rough material in cubic feet is added to each successive kind of labour exercised upon it in superficial feet, in order to ascertain the final value of each piece of stone employed. In ashlaring the price of plain work is allowed to face, bed and joints of each stone, with horizontal bed and one vertical face only for bond-stones, unless they are through stones, when two vertical faces may be allowed. If labour is not charged on any face of a stone, half sawing is to be allowed for each lower face. Columns are measured by taking first two plain sides of the cube, added to the girth of the column as circular planes, and two plain faces to each horizontal joint. The material in solid steps is measured by taking the extreme length, including the tailing in the wall, by the width and whole height. Winders in the same, the width being the mean between the extreme end widths. Labour on steps, if solid, includes plain, sunk, or moulded work on the face of the tread, riser, and ends only if laid on brickwork. To this half the bed is to be added if the step is laid on stone. For cornices, strings and blocking courses set on brickwork add the moulded, sunk or planes in faces and top to the plain work in joints, and allow no beds; but if set on stone, half a plain bed to be allowed besides, also half-plain to the back if worked. For landings plain work is to be allowed on top, edges, and joints. If the underside be worked, to be charged half-plain superficial. Curbs are taken as plain, sunk, or moulded to the three faces, but no bed. For hoisting stone above 10ft. from the ground level an additional 2d. per cubic foot for 10ft. in extra height is to be understood, unless otherwise specified. The second method of estimating masonry recognizes only the exact net cubic quantity of stone used, and affixes a definite and total price to this, varying it only to meet cases, where vast differences of labour are palpably required, and allowing no extra or additional charges whatever under any circumstances. Thus we may have rubble or ashlar, as the case may be, in walls, including all plinths, grooves, arch stones, reveals to openings, string courses, copings, returns, etc., at so much per cubic foot nett, deducting all openings, and backings, if of brickwork, as they may appear in the drawings or in the specifications; in fact, tantamount to a lump sum for the whole piece of work. While it must be admitted that this wholesale method of measuring facilitates the progress wonderfully, it is equally undeniable that it is as uncertain in results as careless in process; and, indeed, the exact and just measurer, even if driven to adopt this method ostensibly, will take the trouble to work out an average block or two of each kind of work upon the other and more correct system, and reduce the cost thus found to a set of prices per cubic foot in the required estimate.

CREDIT VALLEY BROWN STONE

From Carroll & Vick's No. 6 Quarry, Credit Forks, Ont.

SANDSTONE, fine grained, reddish brown. Contains quartz, and a little felspar and mica. The stone is in beds of four feet and under, and can be handled in pieces up to five tons. Quarry 300 yards from Railway.

Specimen.	Section under Pressure	Height.	Crushing Load.	Crushing Stress per sq. in.	Average Crushing Stress per Square Inch
	Ins.	Ins.	Pds.	Pds.	Pds.
A	.....	.....	.....	.....	
B	2⅞ × 3	2⅞	131,000	15,188	
C	2 13/16 × 3	2⅞	130,000	14,751	
D	3 × 3	2⅞	133,000	14,777	14,905

14,905 pounds is the average crushing strength per square inch of our Credit Valley Brown Stone.

The highest standard of test attained by any pure Sandstone in America.

IN confirmation of the facts above stated, we have pleasure in directing your attention to the accompanying table, showing the result of the test of our stone, in connection with the series of tests of building stones conducted in 1892 at the School of Practical Science, Toronto, under the direction of a committee of the Ontario Association of Architects.

By referring to the results of the tests above mentioned, it will be seen that the average crushing stress of the majority of Canadian and American sandstones is far below that of ours, the difference in our favor ranging from 75 to 50 per cent.

The Credit Valley Brown Stone, owing to its modest tone, harmonizes beautifully with red or cream colored brick.

It has been reported that there is difficulty in obtaining Credit Valley Brown Stone. To correct this mistaken notion, we wish to state to architects and the public that we have a large quantity of stone ready to ship on the shortest notice, which can be followed up with an unlimited supply. Last year we made extensive additions to our plant and opened up new quarries and mines, and will supply promptly all orders given to us or our agents.

THE rapidity with which all classes of people, of both sexes, have adopted the use of the bicycle as a means of pleasant exercise and for practical use, has been the subject of general astonishment. When the bicycle was introduced it was regarded by many in the light of a fad, which would disappear as speedily as it came. But time has proved the incorrectness of this opinion. Architects and contractors have found the bicycle extremely serviceable in enabling them to get about rapidly from one piece of work to another. The question of providing bicycle accommodation is one which must be taken into account by the architect when planning for the erection of buildings in the future. The suggestion has been made that the stable should be spacious, convenient to the street and under the eye of the elevator man.

IN this number of the ARCHITECT AND BUILDER appears a fac simile letter from Messrs. Elliott & Son, the well-known firm of decorators, in which they bear testimony to the excellent results which have followed the continued insertion of their advertisement in this Journal. As the authors of this letter have advertised continuously for five or six years past, their testimony is worthy of attention. The fact that the advertisers whose letters we publish handle different lines of goods, though all designed for use in building construction, proves conclusively that the CANADIAN ARCHITECT AND BUILDER is the best medium through which to reach architects, engineers and contractors throughout Canada. Persons who have anything to sell to these classes should be represented in the advertisement pages of this Journal. Will the purchasers of supplies also kindly mention the ARCHITECT AND BUILDER in their correspondence with manufacturers and dealers.

WITHIN a short time quite a marked change has taken place in Toronto in the manner of carrying on business by roofers and galvanized iron workers. Many of those who formerly did only slate, tile and felt roofing have added general galvanized iron work to their business; other firms who formerly confined themselves to sheet metal work are in the field for all kinds of roofing. This has no doubt been brought about partly by the custom of architects in specifying for all iron work which is strictly part of the roof to be included in one contract, and making the roofer responsible for the whole being water tight. There also appears to be a certain amount of retaliation on the part of each trade, caused by the other having taken up the additional line of business. There are strong indications that competition will grow so keen that prices will be cut below a reasonable point. While we would not advocate the restriction of competition in business, we do not think the present condition of affairs is likely to secure the doing of a satisfactory grade of work.

Reference was made in this Journal recently to the financial difficulties in which some church congregations had placed themselves through a desire to worship in expensive buildings. The matter has assumed such a serious aspect that at the last meeting of the Toronto Conference of the Methodist Church the following resolution was adopted: "That this conference is of the opinion that additional guarantees should be provided against the unfortunate tendency that prevails so largely to strain the law affecting the inception of new and the enlargement of existing church enterprises, and recommends that the genetal conference be memoralized to provide legislation which will require the co-operation of the chairmen of districts with the quarterly board in advance of either the enlargement or building of an

existing church, or the formation of a new church trust." The adoption of this resolution may not work to the advantage of architects, builders and supply firms, but there can be no question that it is a step in the right direction when viewed from the standpoint of the churches' interest.

THE seasoning of lumber by kiln drying is a process of recent development and a strictly scientific treatment is necessary to secure good results, more particularly with hard woods prepared for high grade work. It has been found that selections from the same variety of wood grown in different localities require radically different treatment and that perfect drying may be retarded or prevented entirely by too high a degree of heat, especially if applied to lumber soon after it has been put in the kiln. Special machinery and arrangement of the kiln together with experience are as much a necessity in this work as a similar combination of facilities and knowledge is in any other. It is one of the many subjects with which architects should be familiar under the head of growth, formation and chemistry of building materials. We shall not be surprised to find architects specifying ere long that lumber must be kiln dried by a certain process according to the best data available. Another question closely related to that of seasoning lumber is that of preserving wood. It is well known that there are several simple and cheap processes by which the natural resistance of lumber against rotting can be greatly increased. This kind of protection is not used as much as it should be. It is wonderful to see how short a time is required for sound wood in some positions to become thoroughly rotted. The systematic use of preservatives is but little developed and consequently a very great and unnecessary loss is going on always accompanied by insanitary conditions. The remedy for this is largely in the hands of the architects, from whom it should receive more attention.

THE architects of the United States, who have been making heroic efforts to bring about a reform in the method of designing government buildings are greatly encouraged by the strong probability that the present Congress will pass a bill to supersede the Tarnsey bill, in regard to which the president of the American Institute of Architects, Mr. Burnham, and the government officials had such an unpleasant correspondence as noticed in our issue of April last. After that correspondence it was deemed best to proceed by associated individual action instead of officially through the Institute. Several of the architects drafted bills and one drawn by Mr. Post practically satisfied everybody interested. This bill was taken to Washington and after undergoing a number of alterations was introduced in Congress by Mr. McKaig, of Maryland. It is admitted that the modifications suggested by the politicians were all in the right direction and made the bill a stronger and more desirable one than as originally prepared by Mr. Post. Some features of the bill are remarkable and well calculated to make the design and execution of government buildings the highest possible goal of the architect's ambition. To be considered eligible for government competitions is in itself made a high honor, as the bill debars any but an architect in chief of at least ten years practice, and any but those who can cite evidence of sufficient constructive and administrative ability. While the successful competitor will be awarded all the rights and duties of the architect in private practice at full established rates of compensation, very little remuneration will be provided for other competitors. A very modest per diem compensation is allowed to members of the commission who will have charge of competitions. The two features last mentioned are practically intended to limit the cost of the new system, including all expenses for competitions, to the one principal prize, the fee for carrying out the work, and outside of that to prevent any one entering competitions or acting as commissioners from other motives than a generous interest in their art.

THE earnest student of architecture takes upon himself no light task. We think it may fairly be claimed that the student who starts out to qualify himself for an architect, and is determined to master his profession, begins a course which requires an amount of patient and laborious training not exceeded in any line of human endeavor. There is one feature of this work which affords a great relief—the fact that the large variety of knowledge through which he must range is stimulating, and on the principle that change of work is restful, may to some extent be regarded as recreation. But we often think students must be perplexed to decide what is really worthy of acceptance as truth in regard to questions that do not admit of mathematical demonstration. In another part of this number we publish an article on "How to Study Design", which contains some good points, but which would also bear some criticism. The student cannot accept such papers as an indisputable authority, but should cultivate the habit of comparing and sifting different writings on all subjects. Professional societies usually invite those considered most competent to present papers on various subjects and these papers are entitled to consideration. We sometimes notice that two writers, who would stand fairly equal in position and ability, express almost exactly opposite opinions on some matters. Then again strong statements are covered up by such generalities that the student can only understand that something is very wrong or very good as the case may be, but just what that something is, does not appear, so that if he wished to adopt the correct idea and keep clear of the bad he would still be very much in the dark. There seems to be a disposition on the part of many writers to avoid saying definite things about particular parts of work in such a way that faults or merits can be located in existing buildings or illustrated by imaginary examples. We hope to see a change in this respect. Meanwhile students will be safest who take the middle ground, and by careful discrimination seek to find the consensus of opinion among authorities on every subject.

THE contractor's business is always accompanied by risks of loss from many sources. Some of these are entirely beyond his control, and others can only be minimized by carrying on all parts of the business in the most systematic manner. The risks begin the moment a contractor commences to make up the quantities preparatory to tendering on any given job. The risks involved in this part of the business are of two kinds: first, the loss of time devoted to unsuccessful tendering; and secondly, the chances of error in quantities or estimate of values. The total amount of time given by contractors as a body to the work of making up tenders is a very large item, and is one of the channels through which they may suffer continual loss without locating it definitely. That the greater part of the time given to tendering is a direct loss, we think should be perfectly clear to every contractor. Any business man's time has a value for every hour, and if given to work from which there is no return, that value is lost. To illustrate: suppose a contractor who has no business on hand puts in a whole year of solid work in tendering without success in any case if that contractor could have earned any wages in any other way during that time, by just so much has he suffered in actual money loss. The case is not altered by the fact that the contractor may be in a position to stand the loss or that he may have a large business on hand. Some part of that business will be carried on at a greater expense for lack of his personal time and attention. The other risk mentioned, that of liability to error, is one that should not be overlooked. It is hardly necessary to mention how it often happens that a contract is secured by some blunder of omission, and the contractor compelled to do the work at a loss, or perhaps to throw up the job and forfeit a deposit. It also happens that contracts are lost through error of getting figures too high. This is better than to err on the other side, but it is nevertheless far from satisfactory. These difficulties cannot altogether be overcome, but every available means should be employed to reduce them to a minimum. The contractor's business grows out of the demand for an agreed price for certain work, and prices cannot be given like a merchant's price for goods on the shelves, but require careful calculation in each case. No one is proof against making errors, but safeguards can be used which will afford protection from them. The different tenders for any work if carefully and intelligently prepared should not vary from each other more than ten per cent., but it is safe to say the difference is generally greater than this. A more general custom of having bills of quantities prepared by a professional surveyor —a method common in England but seldom used here—would be found of great value in bringing about more uniform tendering. By this means contractors would also effect a saving in

two ways—in the time necessary to make up a tender, and in the reduced possibility of error. Allowing that the cost of the surveyor's services be paid by the contractor there would still be for the latter economy in this system; and we believe that contractors who might feel themselves quite competent to make up their own estimates, survey and all, would find a reliable bill of quantities well worth its cost purely for the purpose of comparison with their own figures. Such a system is also helpful in preventing friction between architects and contractors. In some cases it would call for greater care and definiteness in specifying, and all such influences are beneficial to all parties to a contract. While architects would no doubt be pleased to see a reform in the direction indicated, it is not likely to be brought about unless the initiative is taken by the contractors.

TRADE COMMISSIONS TO ARCHITECTS.

An English architect sends to the Builder for publication a circular addressed to him by a firm of manufacturers of building materials, in which a commission is offered to him on such of the manufacturer's materials as he may specify for use in his practice. Exposure of similar methods has from time to time been made in the American architectural papers. Much has properly been said in reprobation of manufacturers and supply firms who seek to secure business on this plan. The British Architect, however, presents another aspect of the case when it says:

"If one asks why Brown, the stove grate man, offered Robinson, the architect, a commission on the sale of goods, one is tempted to think of the number of Joneses who must have given Brown some direct encouragement to believe all architects were equally susceptible of being approached in a similar manner. A black list of manufacturers who offer commission to architects might be a useful thing, but a similar list of architects who receive it might be a more effectual cure. Some architects don't take commission from manufacturers; they receive presents. They ought to be included in the list. If Jones receives 15 per cent. commission, and Smith accepts an umbrella or a chimney piece ornament, there is no difference in the quality of their offence. They both sell their independence for what, in the opinion of the manufacturer, it is worth. That apparently is not much. It is easy to put the manufacturer into the pillory for offering commission to architects. But there is no smoke without fire, and if all architects, or even the greater proportion of them had always promptly and decidedly rejected any temptation to receive commission from manufacturers, we have an idea the "custom" would practically be dead now. To the manufacturer, no doubt the practice appears to be but that adopted in the pushing of every business. That he would be glad enough to be quit of it goes without saying. It is an expensive and awkward procedure at the best of times. There can be nothing more fatal to honest building and good architectural results than the passing of commissions from manufacturer to architect. The architect loses his independence and self-respect as a professional man, and the manufacturer comes to depend more upon the offering of percentages than the quality of his goods for the extension of his business. But whilst it is impossible too strongly to condemn the system, let it not be forgotten that there are two sides to the question and that it takes two to complete the transaction. Those who receive commission are as much to blame as those who offer it. Are the manufacturers wholly to blame? We think not. But it would need a great deal of courage and independence on the part of any firm of manufacturers to attempt to prove the contrary. A list of offending architects would be quite as interesting reading as that of offending manufacturers."

There is unquestionably ground for this view of the subject. Some Canadian architects are not held to be above suspicion in the matter of accepting bribes. For example, a cement dealer who recently sent samples of his material and circulars to an architect in an Ontario city received in reply a letter from the architect in which he stated that he wished to lay a concrete floor in his cellar, and requesting the dealer to send him enough cement for the purpose. Here was a plain intimation from an architect that he was open to a bribe. In the light of such invitations to wrong doing, it is not to be wondered at that the honest architect finds himself approached with offers of commission and undue influence in other forms. Such practices are highly demoralizing to all concerned, and the influence of architects, manufacturers and dealers of integrity should be exerted in an endeavor to stamp them out.

The builders of London, Ont., held a very enjoyable picnic at Port Stanley a few days ago. A baseball match, a tug of war, and a baby show were among the prominent features on the programme.

COMPETITIONS.

The Ministry of Public Works, Cairo, invite competitive designs until March 1st, 1895, for the new Ghizeh Museum to be erected in that city at the estimated cost of £123,000. The first premium will be £630, and £420 will be divided among the four architects whose designs are placed next in order of merit. Some of our Canadian architects, whose fancy has been running in the direction of Egyptian architecture, should stand a good chance in this competition.

We are informed that no decision has yet been reached in the competition for designs for a public library building at London, Ont. It is reported to be the intention of the Library Board to appoint Mr. O. A. Graydon, City Engineer, to be the judge of the merits of the designs submitted, and to make the selection of the most suitable plan. At last accounts, however, the plans had not been placed in Mr. Graydon's hands.

ILLUSTRATIONS.

MISSION CHURCH, BRANTFORD, ONT. E. SWALES, SHEFFIELD AND DONCASTER, ENG., AND H. ETCHES, M.I.M.E., (LOND.) BRANTFORD, ONT., ARCHITECTS.

This church is designed to seat 204 persons. The foundation and outside walls are of brick faced with rough dressed stone, with half timber work above. The roof is boarded to purlins in narrow widths, jointed, covered with felt and shingles, with red ridge cresting. The total width of interior is 25 feet, total length, 70 feet. The interior is divided up into five bays with six frame principals.

DESIGN FOR PROPOSED STATE CAPITOL AT OLYMPIA, WASHINGTON TERRITORY.—R. MACKAY FRIPP, F.R.I.B.A. ARCHITECT, VANCOUVER, B. C.

THE ROUND CHURCH OF ST. SEPULCHRE'S, CAMBRIDGE, ENGLAND. FROM SKETCHES BY ANDREW T. TAYLOR, F.R.I.B.A., MONTREAL.

SMALL HOTEL AT VANCOUVER, B. C. R. MACKAY FRIPP, F.R.I.B.A., ARCHITECT.

TORONTO BUILDERS' EXCHANGE.

MEMBERS of the Toronto Builders' Exchange, their families and friends, numbering about 150 persons, enjoyed a pleasant days' outing at Wilson Park, N. Y., on July 27th, the occasion being the annual excursion and picnic of the Exchange. The comfortable steamer Garden City carried the company to and from the picnic grounds. The weather though very warm was bright and clear, and when tempered by the lake breezes and the shade of the grove was thoroughly enjoyable.

The excellent music discoursed by the string band which had been engaged to accompany the excursion added not a little to the pleasure of the trip.

Three or four hours were pleasantly passed at the park in boating, bathing, games for the children, etc. Nor must we omit mention of one of the most exciting events of the day, viz. the annual base-ball match between nines representing the Builders and Supply Merchants. The rival teams were composed as follows:

Builders—T. Cannnon, Jr. (Capt.), J. Crang, H. Lucas, Wm. Saulter, John Hanrahan, J. Murphy, —— Bedford, J. Thomson, J. Little.

Supply Merchants—John Maloney (Capt.), W. Whillans, A. Dickey, Isaac Price, G. Oakley, J. Oakley, J. Donovan, M. Ryan, T. Rattledge.

Umpire—T. Stewart.

The game was watched with much interest by the friends of the players, and every exhibition of good play was enthusiastically applauded. Nor were such exhibitions few and far between, as might be supposed, seeing that many of the players only enter the field once a year.

At the close of the game the score stood—Supply Merchants, 9; Builders, 8.

The company bade farewell to the park at 5 p.m. and shortly after 8 o'clock were safely landed at the Yonge street dock.

For the success which attended the event, credit is largely due to the following gentlemen who composed the committee of management: William Forbes, Chairman; Thomas Cannon, John Aldrich, David Williams, Isaac Price, William Booth, John Barnard, Thos. Murray, Geo. Oakley, Henry Martin, Frederic Bayliss, James Craig, John Murphy, Benjamin Brick, William Park, Wm. Whillans, John Phillips.

It is hoped that this annual excursion and picnic of members and friends of the Exchange will be maintained and become increasingly popular.

(Correspondence of the CANADIAN ARCHITECT AND BUILDER.)

The authorities of St. James Cathedral have commissioned Mr. Vincent, a local sculptor, to proceed to Rome and study carefully Bernoria's famous canopy in the Basilica of St. Peter, in order that he may be able to reproduce a perfect copy for the cathedral here. This copy will measure 43 feet in height and will be embossed in bronze.

It is to be hoped that the exhibition of improved fire appliances in connection with the recent meeting of Fire Chiefs in this city was an object lesson which will not be lost upon our city authorities. The fire loss in Montreal in recent years has been abnormal and has necessitated the payment of high rates of insurance.

The students examinations of the Province of Quebec Association of Architects which were announced to take place in July, have been postponed until January with the consent of the candidates, who are few in number. The January examinations will take place in Quebec.

MASTER PLUMBERS' ASSOCIATION.

The committee of the Master Plumbers' Association appointed for the purpose of preparing a constitution and by-laws for the Association have completed their task, and at a general meeting of the craft held on Aug. 3rd, the constitution and by-laws were discussed and adopted. The meeting adjourned until Thursday, August 9th, for the election of officers. At a meeting held on that date the following officers were elected:

Executive Board—J. Lamarche, President; John Date, 1st Vice-President; Alphonse Champagne, 2nd Vice-President; Henry Padden, 3rd Vice-President; W. M. Briggs, Secretary; Joseph Gibeau, French Corresponding Secretary; J. W. Hughes, English Corresponding Secretary; P. Leclerc, Jr., Financial Secretary; W. A. Stephenson, Treasurer.

Sanitary Committee—J. W. Hughes, Chairman; John Date, Jas. Mattinson, A. Sigouin, J. C. Jactol.

Audit Committee—J. Watson, Chairman; P. Desforges, T. Jacotel.

Arbitration Committee—P. Carroll, Chairman; A. Demers, George Von, Geo. Rosser, H. Bailey.

Apprenticeship Committee—W. Britton, Chairman; E. C. Mount, A. Cardinal, J. Sadler, A. Blais.

Legislative Committee—F. Brunet, Chairman; D. Gordon, D. Ouimet, J. Burns, P. Leclerc, Jr.

General meetings of the members of the Association will be held on the 1st and 3rd Thursday of each month at St. Joseph's hall, corner of St. Catherine and St. Elizabeth streets.

LEGAL.

Messrs. Brown & Love have entered suit against Mr. E. J. Lennox, architect for the new city and county buildings at Toronto, to recover the amount of a cheque for $7,000 which they they deposited with their tender for the completion of the building. Messrs. Brown & Love's tender was accepted and they entered upon the work, but subsequently withdrew because, as they allege, they were unable to continue owing to the litigation in which the works were involved. The architect claims that by withdrawing from the work the plaintiffs forfeited their deposit. He will therefore retain possession of the money until instructed by the courts what disposal should be made of it.

Application is made for incorporation by the Crown Pressed Brick Company, of Ottawa, with a capital of $100,000.

STUDENTS' DEPARTMENT.

USEFUL HINTS.

Moorish fretwork is becoming more a favourite than ever. It is used most successfully when varnished, but not painted. Paint destroys to some extent the sharpness of the outlines.

A good egg-shell polish for fancy woods may be made by dissolving together in 40 parts of alcohol the following:—Three parts of shellac, 1 part of gum mastic and one part of sandarac gum. The polish may be applied with a brush or cloth.

When it is desired to paint ironwork in exact imitation of stone, let the last coat of paint be very thick and be applied quite freely. After it has commenced to dry dust on sandstone crushed and reduced to powder. If the paint is of the same colour as the stone the imitation will be a very natural one.

MOUNTING PHOTOGRAPHS.—Starch dissolved in water is a good material for fixing mounts to photographs, and not so liable to discolour the photo afterwards. To fix them, have two pieces of plate glass, or any other kind of material similar, place the mount on one, and having smeared the photo with the prepared starch, place it in its proper place, then put a sheet of blotting paper and the other plate of glass, &c., and a sufficient weight to press the photo perfectly to the mount. Let it remain a few hours, and then remove the glass, &c.

A ceiling that is coming to be very popular for cafes and restaurants, and some of those drug stores that depend largely on their soda fountains for their revenue, is made of square glass panels, separated by narrow wooden moldings, the back of the glass being marbleized by some such process as that used in marbelizing slate for mantles, while occasional panels are filled with decorative designs. The effect is very similar to Mexican onyx or polished marble, and is specially adapted for all such purposes. Narrow brass bead moldings would look particularly well to separate the panels, though they would be somewhat expensive.—Painting and Decorating.

THE USE OF TIMBER.—To obtain the greatest strength in timber beams, joists, rafters, and breastsummers, the depth must greatly exceed the width—the greatest strength opposed to the greatest strain. A joist 6 by 3 will bear twice as much if put edgewise as it would if laid flat. If the weight to be supported be in proportion to the length, then, the width remaining the same, the square of the depth divided by the square of the length ought to be the same also—i. e., the depth of a joist ought to be in direct proportion to the length, and for stiffness the width proportionate to the depth. Where the question is of a piece of timber supporting itself, the weight is as the length multiplied by the depth, and we must multiply this again by the length for a divisor. A rod of fir 1 in. square, or a plank 10in. by 1 in. laid flatwise, would keep quite straight with a bearing of 5 ft. A piece of timber 10 in. square would swag very much with a bearing of 50 ft.

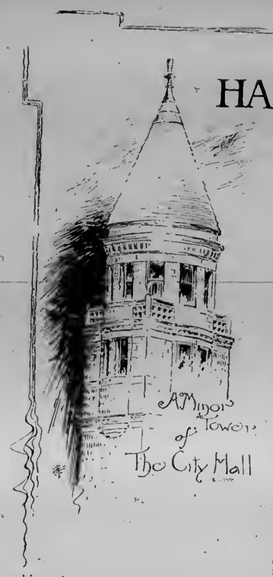
PAINTING IRONWORK.—At a meeting of the Association of Engineers of Virginia, Mr. S. Wallis dealt with the painting of ironwork. He recommended that the first coat should be red lead ground in raw linseed oil, used within two or three weeks after mixing, and kept thoroughly mixed when in use. This coat would dry in from twenty four to thirty hours. For a black finish the next two coats should be made up from a paste composed of sixty five per cent. of pigment and 35 per cent. of raw oil. The pigment should consist of sixty-five per cent. of sulphate of lime and thirty per cent. of lamp black, to which should be added five per cent. of red lead as a drier, the whole thinned to a proper consistency with pure boiled oil. For a red or brown finish the paste should contain seventy-five per cent. of pigment and twenty-five per cent. of pure raw oil. The pigment in this case would consist of fifty per cent. of sulphate of lime, forty per cent. lime carbonate as a drier. Lead paints were not recommended for finishing coats on account of chalking, nor zinc paints on account of cracking.

INTERCOMMUNICATION COLUMN.

This column is intended to afford a means of correspondence for students, builders and all our readers desiring information they cannot otherwise obtain. Questions for which an immediate reply is required should be marked "Urgent." Names and addresses of correspondents must be sent with their communications, but these may be signed with initials or otherwise for publication.

"Quiz" writes: Can you give me a satisfactory method of measuring chimney shafts?

ANSWER.—Take them as solid, work them out cube, and reduce it to superficial 6in. work, and then allow a certain amount for parquetting, in which case, you must use your judgment. To measure brickwork reduce the superficial measurements of 18in. to a standard thickness—i. e., 9in.—deduct all openings, and allow a certain amount for bedding window frames, &c. The angles of brickwork are not as a rule charged any extra, this coming in the price for 9in. work. Reduced moulded brick jambs are measured lineal, and arches are given in quantity at so much each; of course, price depending on what kind of arches they are. Eave courses are measured lineal.



HAMILTON

THE competition for designs for a House of Refuge has been decided by a vote of the aldermen in favor of Mr. Barber, who has recently joined the ranks of local architects in this city. I learn that in this competition there were eight or ten competitors. There were no well-defined rules for the guidance of competitors, and no person with any knowledge of architecture was called in to assist the Council in deciding on the merits of the designs submitted. There is dissatisfaction, of course, as under such circumstances it was a foregone conclusion there would be. Unless architects show their esprit de corps, and unitedly refuse to take part in competitions which are improperly planned, they must expect to suffer disappointment and injustice. As to the merits of the accepted design I have nothing to say, except that the architect has been so hurried for the purpose of getting the work ready for tender, that it is impossible that he can have been able to do any deliberate thinking on his design. The cost of the building will be in the neighborhood of $17,000.

Mr. Mills, a local architect, is seeking to recover by legal process from the Hamilton, Grimsby and Beamsville Electric Railway Co., the sum of $100 for sketch plans for a power house. The defence contend that the plaintiff's claim is excessive. The judge has the matter under consideration.

THE MARITIME PROVINCES.

(Correspondence of the CANADIAN ARCHITECT AND BUILDER.)

The Chignecto ship railroad is again exciting considerable interest. Persons who were favorable to the scheme are more anxious than ever that the railway should be completed. They point out that the completion of the work will prove a great and lasting benefit to intercolonial trade and transportation, that the shipping of the Gulf of St. Lawrence country would be greatly developed by such a road, and that the work of all maritime shippers would be greatly facilitated. On the other hand there are those who are opposed to the scheme on the ground that it involves a foolish expenditure of thousands of dollars, and that no adequate commercial advantages could be derived from its construction.

A short history of this great undertaking will no doubt prove interesting to the readers of the ARCHITECT AND BUILDER. This railway was designed as a substitute for the Bay Verte Canal to unite the waters of the Gulf of St. Lawrence with those of the Bay of Fundy. The canal has been agitated ever since the early settlement of the country, and, after a voluminous amount of evidence had been taken, was favorably reported upon by the canal commission. The cost was estimated at from $7,000,000 to $14,000,000, according to the design. The work was actually put up to tender by the government, but was postponed, owing to a proposed change of route. After a great deal of talk and correspondence the canal scheme was abandoned, and a few years later a ship railway was proposed as a private speculation, to be assisted, if successful, by a government subsidy for a term of years. English capitalists were induced to consider the scheme. They were favorably impressed with it, and in 1882 an act of incorporation was obtained.

Sir John A. Macdonald gave a good deal of study to the project, and he finally became an enthusiastic supporter of it. He made a personal canvas of public men, and it was largely on account of his influence that the government voted $170,000 to the company to be paid, commencing one year after the completion of the line, and ceasing if at any time it failed in operation. The company consisted of railway men and capitalists in England with Mr. Ketchum as engineer. The work was commenced in October, 1888, and continued vigorously until July, 1892, when the contractors were obliged to suspend work owing to their connection with Argentia, the financial collapse of the Baring Bros. having shattered their resources. At that time the company had expended $3,000,000 in the work. It is now more than half completed. Nearly all the rails have been laid. Work on the dock at the Amherst end of the line is well advanced. The massive stone masonry has been very substantially constructed. A great deal of work has also been done at the Lidnish end of the road. The company calculate that $1,500,000 will complete the job. The money has been subscribed, but the subsidy act has expired and the government has been asked to renew it. It seems to be demurring slightly just now, but persons who are in a position to give a pretty correct idea about this matter say the extension will be granted. It is pointed out that in view of the fact that the company has expended some $3,000,000 in the work, and the government has expended nothing, and has therefore suffered no loss by the delay, the country has in no way received any damage by it, and therefore not to grant the company an extension of time, would, to say the least, be unjust on the part of the Dominion Government, when it is considered that the suspension of the work was in no way due to carelessness of the company, but altogether to a circumstance over which they had no control.

Mr. Ketchum estimates that of the gulf and bay ports, 600,000 tons of freight would pass over the railway the first year. The traffic would be between Upper Canada and the Gulf ports on the one hand, and the Bay ports, the Atlantic ports of the United States, and the ports of the West Indies on the other hand. The agricultural and fish products of Prince Edward Island, the coal and iron ores of Pictou, and the small lumber of the north shore would be carried to American markets over this road. From the western provinces would come flour, meal, grain, meats, hides, &c., to St. John, there to be exchanged for southern products and other merchandise. In the way of return trade there would be sugar, molasses, cotton, coffee and other southern products from the West Indies and from South America. Coal from the Cumberland and Joggins, Nova Scotia, mines for the west would also be carried.

A. H. McC.

REMARKS ON ESTIMATING.

THE first thing a young builder should do before commencing to make an estimate will be to provide himself with a list of items requiring to be done on the proposed work, and the styles, qualities and amounts of materials of all sorts necessary to complete the work. Having them on his memoranda, and a goodly supply of catalogues and price lists within reach, he may then commence work at once.

Excavating for foundations will be the first thing to consider, and in order to get at the cost of the work closely, he should know the character of the ground, whether clay, gravel, sand or other material; then he must know what it must cost per yard to remove this, and where the surplus is to be dumped. Drains will next require his attention: the number of feet, size and style of drain, cost per foot laid in place and covered, including all traps, joints, angles and connections. A survey of the site—which the estimator may make himself—will give a correct idea of the grades and the amount of digging to be done, which should be accurately measured and charged up.

Next comes the stonework, including the preparations for the footing, which may be piling, concrete, or simply rammed. In either case, the time and material must be considered and provided for. Cost of footings and putting in place should be a separate item. The stone walls follow, including all dwarf walls, buttresses, piers and separate foundations for chimneys, fire places, etc. Remember, in stonework, the mason measures the outside girth, which gives him the benefit of one thickness of wall at each angle. Provide for damp course between stone and brick, which may be of slate, lead or asphalt, as the specification may direct. Do not overlook relieving arches over all openings, both in stone and brickwork, as they require more time to construct than the ordinary wall. Openings in rubble stone work should be charged up solid, as cutting and waste costs as much as though the wall had no break in it. One cord of stone, of 128 feet, will measure in the wall scant 100 feet. It is better always to allow 96 feet of wall for every cord of stone: this of course means 96 square feet. Worked stone measures the same in wall as on the ground.

The foregoing merely gives an outline of the course to be taken by the estimator. Commencing with the excavating, he should continue until every item required to complete the structure in every particular has been provided for; bearing in mind all the time, that the smallest thing about a building costs money, and if he should overlook any item, by a loose system of estimating, he will find at the close of the work, that his profits will be cut down in proportion, as the architect or proprietor will justly demand that the overlooked items be furnished at the contractor's cost. It will not do to lump the small items, as is frequently done by unsuccessful or careless estimators, for the lump sum may be greatly in excess of actual cost and fair profit, and may cause the estimate to be too high, or it may be too low, thus causing a serious loss.

The successful estimator generally has on his desk, when figuring on a piece of work, what is technically called a "tickler." This may be a small book, or it may be a series of cards, on which are written all the varieties of labor, skilled and otherwise, required upon any style of building, with prices by day or by piece work, when such is available. Also the prices of materials of all sorts and sizes, including lumber in all states, stone, brick, hardware, glass, plumbers' goods, roofing, paints, oils, &c., &c. Having a list of this kind before him, with prices attached, the estimator will not be likely to overlook any item in the proposed building he may figure on.

The items in the "tickler" should commence with: Laying out the ground for foundation; digging drains; excavating for cellar and foundation: drain tiles or pipes, foundations, walls; then all the items required for this work, including concrete and cement for cellar floors, or brick paving, if such is used. The superstructure should follow, with windows, doors, floors, furring, partitions, stucco-work and plastering, &c., and every particular in connection with the work. Then comes the carpenters' and joiners' work, including putting down floors, putting up trim, building stairs, hanging and trimming doors, putting in sashes, weights, pulleys, &c. Painters' and finishers' work follow, including all necessary materials and labor. Then follows heating, bell hanging, lighting, &c.

In a future paper I will submit a form of "tickler," which I think may be found useful to country builders when making estimates of work costing not more than $3000.

A. Z. Z.

The School Supply Co., of Berlin, Ont., are developing a talc mine near Sharbot Lake. The talc is manufactured into crayons for school purposes.

HOW TO STUDY DESIGN.*

Is it possible to design in harmony with the spirit we live in, or to distinguish between the archaeological and architectural beauty of ancient buildings? Why cannot we design buildings as an engineer designs an unsophisticated iron bridge without the result being hideously ugly? Will not the terrible buildings of the Victorian Gothic era with which our land is bespattered have in the eyes of succeeding generations the same beauty (is it architectural or archaeological?) that the crude Classic productions of the Jacobean and Queen Anne periods have in ours? and if so, why do we not see the beauty of our bad architecture? Are not we perhaps on the wrong tack altogether, and only manufacturing picturesque grottoes of ancient relics, while the genuine and characteristic architecture of our age is to be found in the works of engineers, mill and factory builders and gin-palace fitters? Are the congeries of Mediaeval and Classical oddments, whether in plan or detail, that compose our Domestic and Ecclesiastical architecture, really works of national art? Are not workhouses and hospitals or a Metropolitan Tabernacle or railway station interior nearer the mark? Do not architects, as far as their revived pedantries of Art are concerned, run a great risk of becoming mere exotics, useful perhaps in arranging the business of a building, but to the world at large as artists, idiotic in expression and utterance?

Can architecture as now practised by its professors continue to survive when the *debris* of the ages has been rummaged through and there is nothing new to revive—when the history of architecture has been learnt in vain, and the poor history-bred architect can no longer find fountains for prigging ready-made details from? Must we really come to the conclusion that clothes can only be made on old patterns, patches and defects included, and only artistic pictures painted of bygone times and not of our own? Is there not beauty or pathos, simplicity of wondrous complexity in our own extraordinary age, with its incessantly varying developments that the architect can reflect in the buildings that he designs for its accommodation? Cannot we hope that some seeds of true architecture may be sown in our work-a-day buildings that may develop into a detailed style possessing true beauty? Does the barren unphilosophical study of our present authorities assist us one whit, or even suggest to us the idea that our own age is the outcome of history, and that we should pursue its direction and learn its lessons of the motive of its soul rather than bark back again and again to the mere outer forms of nothing but bygone art "as if that soul were dead?" We may well ask ourselves the plain question, whether if the so-called history of architecture comprised in illustrated authorities, a list of which would be short and easily made, was laid as much aside by architects and their educators and examiners, as, say, the history of ornament is, though for no given reason—perhaps it is mere forgetfulness—we should be able to design at all? Imagine yourself, if you can, sitting down to design a church or a house in the country with the stipulation that you were not to revive any ancient style in your building, and does not the thought seem both absurd and painful? If so, take for your subjects either a factory, say for boot blacking or fancy soap, or a railway station block, in which it ought to be both absurd and painful to employ any ancient style, and see how you would be able to get along without the seemingly indispensable history. And yet if history teaches us anything as to the sources of life and motive in design, it shows that the Greeks had little or no history of architecture to draw upon and revive, and that the Goths, who probably knew little or nothing as to ancient Art, deliberately set aside the productions of their ancestors, even as types, and thought and acted for themselves alone. Can anyone say that the results do not justify their methods of study, and shall we be forced to accept as a conclusion that the less we have of the study of architectural history as at present conducted the better?

Let us return to our examples. The results of your efforts to design either a factory or a railway block would probably be satisfactory and negatively beautiful in proportion to your regretful resignation to the facts of the case, and to your own ignorance of the pictures in your own architectural history books, or, in other words, of what different people had done under differing circumstances elsewhere. What positive beauty your work possessed would consist in the manifestation of your skill in the choice, contrast and arrangement of materials, in the proportions of your building, in its balancing of voids and solids, its recessings, in its simplicity or variety of line, its unaffected expression of purpose and skilful adaptation to use. Every one of these qualities should be equally evident in the more monumental or domestic subjects, such as the church or country-house. The church having no obstructions to sight, and being perfect acoustically, and with the house rejoicing in pure plate-glass windows where necessary, with further qualities such as a perception of the poetry of scale, of rhythm in contrast or repetition of grouping and perspective, of mystery and distance, with fancy at work on the detail, applied perhaps unconventionally, but always where most effective in execution, and either emphasizing construction or decoratively masking it, suggesting intellectual composition as well as picturesque freedom, the harmonious arrangement of features as well as the application of free ornament and many other ideas in design, with play of light and shade, effects of lighting and schemes of color, all open to the student cut adrift from the modern school of architecture, and an interesting building having naturalness of purpose and real beauty is almost assured so long as each quality of use and fancy is exercised with reasonableness and decency. Some difficulty may occur to the mind as to the quality of ornament not cast in ancient moulds, but the same elements of beauty govern and compose ornamental detail as general architectural design, and there is ever open to the ornamentist the fountain of Nature, which, unlike ancient and traditional sources, is infinite as the sea. Let it not be supposed, however, that by ornament derived from Nature naturalistic ornament is meant as the forms of Nature copied in carvings or paintings. The material and the purpose of the ornament, and many other circumstances, must control the conventionality of its treatment. Remember that a world of art and design exists between the Parthenon frieze and the actual horses and men that Phidias saw around him, and that if intellectual discrimination is not used in the translation of form and matter, and design is not interposed between Nature and ornament, no beauty will be the result. But this is at present a digression apart from carvings and paintings. How about mouldings, capitals, cornices and purely architectural forms? Can these be designed except by ignoramuses, apart from style and precedent? Most certainly. In your blacking factory example you may only require a dignified and simple cornice of brick and stone to crown the wall, and though, from pure poverty of imagination and defective training, you may have no other resource than a doubly-debased Greek molding, there is the conceivable possibility of a simple contrasting arrangement of light, shade and elevation considered in relation only to the wants of your front, and also a possible combination of line in contour of curved and straight members, forming a harmonious whole that shall be satisfactory and yet original, furnishing evidence of independence of thought and perception of beauty to your professional critics. This may sound impracticable, and we expect to be told that ancient styles are the languages of the art of architecture, that their forms and details are its words, and that our fine imaginings without such words and diction are vain and utterly incapable of realization. That we must learn these languages as part of our education, and trust either to heredity or to fickle fortune to teach us what to say and how to say it. Learn your styles, master your Orders, copy them carefully, drum them into your memory for a senseless reproduction as mere forms, and you will be qualified to become a student of a dignified architectural school, and in addition if you cram up the mathematics of the proportional ratios, count the columns of the Parthenon and master a few pedantic technicalities from Gwilt's *Glossary of Terms*, you may pass the Art section of a qualifying examination. That the training adopted to this end has its uses cannot be denied, for all training is valuable, and as an introduction to the study of archaeology it may be definitely useful, though this is very far removed from the cultured dilettanteism in which it took its rise; but to the architectural student it is purely incidental, and as at present conducted, the study of the styles of antiquity is in no sense a qualification for the practice of modern architectural design.

We are living in an age distinguished above all others for its inventive genius—the prime essential of genuine architecture—for wealth, another essential to the practice of architecture. Having a profession of admiration for the arts—famed for municipal enterprise—an age, too, of unexampled peace and prosperity. But architects, instead of growing in public esteem as artists, are losing ground yearly; their works, instead of being characteristic of the whole spirit of the age, only illustrate their own personal fads and fancies and their love for the passing whims of the day. The whimsicalities of the gentler sex with regard to the latest fashion will not exceed in grotesque flightiness the eccentricities of the architects of the last few generations, as illustrated in their periodical fashion-plates of buildings, when they are reviewed, say, at the jubilee of the Architectural Association. To what esoteric impulse are the gyrations of the muse of architecture due, if not to the error of imagining that the past is the present, that ancient means modern, and that archaeology is architecture? What accountable idea underlies the continuous and futile reproduction of architectural antiquities in modern design? Why should a consistent and enlightened race such as English produce, through their architects, within a century, such anachronisms as the National Gallery and the Royal Courts of Justice, or public statues, either clothed in nothing but sheets without canopies or in full modern dress (gilded), covered by baldachinos, and surrounded by unprotected figures, mostly females, only ideally clad? What rational theory of architectural design, apart from archaeology, can reconcile the production of St. George's Hall, Liverpool, with the Houses of Parliament at Westminster? Will not posterity justly conclude upon abundant evidence that the Victorian architects were petty-spirited, out of sympathy with their environment, each bent on vindicating some absurd archaeological revival wholly unsuited to their buildings, and wasting their eloquence in incriminating the age which gave them birth as lacking faith, as Philistinic in spirit and cruel to all the arts, and in bewailing the hard fate that did not cause them to be born barbarians or feudal serfs? And yet our age cannot be said to have lacked men practising as architects, possessed of genius and talents of the highest value to architecture, with inventiveness, perception of beauty and form, of wide artistic sympathies, and of remarkable adaptability of style. The English architects of the various revivals have been men of eminent gifts and enthusiasm for their art, and probably without their equals among European nations. The Greek revival, based upon the work of Stuart and Revett, Wilkins, Cockerell and others, was no mere artistic fad; these men were profound archaeologists, and the combination of artistic instinct and antiquarian learning displayed in such works as the beautiful Hanover Chapel—doomed, shall we say, through the apathy of architects?—the entrance to Euston Station and University College, London, is worthy of unstinted admiration. There is a thoroughness of historical study manifest in these buildings that compels praise; in each case a lofty ideal conception has been attained, and a completeness of architectural feeling for every detail that betokens the earnest designer. Yet in each case the manifest powers of design possessed by the architect have been concentrated upon designing a Christian church as a Greek would have designed

*Paper read by Mr. A. Beresford Pite, A.R.I.B.A., before the Architectural Association, London, on November 10th, 1893.

a temple, an entrance to a station-yard that is but an enormous tribute of the art of architecture at the throne of the railway demon, and the sacrilege that for more than a generation was but a feeble outbuilding to a portico which was an approach to emptiness. In each instance the march of time and the progress of national life have branded the works on which the architects bestowed such earnest care as anachronisms.

The Gothic revival which raged in its turn after the Greek, and had an Italian rival as well as offshoots of its own to compete with, commenced, flourished, died, and is condemned upon the same archaeological ground as the Greek movement we have just described. The presence of rivals produced friction, and the contesting archaeologies each claimed antiquarian precedent only as their ultimate test of beauty. Is it not utterly illogical and ridiculous to reflect that the beauty or propriety of nineteenth-century architecture should be judged by the accident of birth to some detail either in the twelfth or thirteenth century of some corresponding epoch? Traces of this error can be still observed in architectural examination question papers. In ecclesiastical design the iron bondage and dead weight of antiquity was endured longest, but when the evident revolt came it was only to resort to foreign types for a while and then to some period of hitherto forbidden fruit at home. The absurdities of most of this work are manifest to us now, but it is only a very short time ago that tremendous efforts were made to combine incompatible elements, and to compel the nineteenth century to wear the cast-off clothing of its Mediaeval ancestors. But all dead men's clothes soon wear out and want replacing. What shall we say to the revivals of the use of indistinct glass in small pieces fastened together with lead straps, of rough rubble walls unplastered, of chilly paved halls, of wide-mouthed, open-throated chimney openings, of confining the influence of the fire-place to the ingle nook and numberless other barbarisms that have made us laughable to the world at large? And to what other lengths of imitative foolishness will not this historical method lead those who will blindly and unthinkingly follow? Apart from all questions of use or comfort, what beauty of form or of architectural idea is there in half the tricks of design and construction by which a modern building is made ancient in character. Put aside the fact that the Goths did so, we could give no reason, good or bad, for more than half of modern Gothic architectural design. The disposal of thicknesses in walls and buttresses, the scantlings of roof timbers and their framings, are governed by considerations which were good in days when walling was not paid for by the rod and timber was not purchased in scantlings at the Surrey docks. The fact is that English architects have been first bewitched with one beauty and then with another, and have finally endeavored to be in love with all the beauties at once; in losing their hearts they have lost their heads, and have lived in a Mediaeval dream of bliss while the nineteenth century marched on and left them farther and farther behind in what is really a morass of archaeology, out of which no path to real living architectural design can emerge.

As we endeavored, however, to give the modern Greek architects their due, those of the Gothic Renaissance must not be dealt with unfairly. We are to this day living under the romantic charms of their Mediaeval England, and it is doubtful whether we can fairly gauge the verdict of the future on recent work. Great perseverance and consistency, an exact thoroughness of observation, a quick perception of the artistic qualities of picturesqueness, local beauty and appropriateness; a widening sympathy, still at work, for all the crafts and arts connected with home and civic life that flourished alongside architecture in Mediaeval England; a general soundness and simplicity of construction equal to that of the Mediaeval master builders, characterize the work of the leaders among modern architects of the Gothic revival. These men have absorbed themselves entirely into the spirit of the past age, and have succeeded in attaining their ideal to live architecturally in the Middle Ages, and they can and do produce for us genuine works of Art in all branches that compel admiration. Take a country-house by a leading architect of the present day for an example; how picturesquely its rubble and half-timbered walls group themselves upon the hill, with what stern reserve the battlements crown the walls, and behind them at sufficient distance to allow of the passage of a cross-bow man rise the quaintly waving tile roofs. How the tower crowns the landscape, with what a sense of protection the high courtyard walls enclose the entrance. What broad unwindowed surfaces of wall seem to defy the missiles of pre-explosive warfare. The mullioned and latticed windows, the timber framings, the stone jointing, the ancient leaden conduits, the very grin of the gargoyles all bespeak the thoroughness and perfection of the Mediaevalism, which only consummate talent could realize for us in this un-Mediaeval age. How thoroughly the artist has grasped his problem, too. Side by side with the architectural consistency one is conscious of a subtle artistic charm that seems to catch and secure effects in the modern building that the hand of time alone effected in the old prototype. The harmony of color given only by age is sought for, the rapidly weathering tiles, the dark-toned bricks, the fumigated timbers, the colored pargetting all are carefully considered and deliberately carried out to fix the Mediaeval impression upon the mind and emphasize the doctrine that nought but what is old can be beautiful in this grossly unartistic age. The internal arrangements are even equally Mediaeval. With the homely charm of an ancient grange is combined the charm of a modern house, but the essence of the charm is its antiquity. Hence, the quaint crookedness of plan that produces picturesque passages, the variety of levels, the deep window recessings, the great hall, the beamed ceilings, the panelled linings, and numberless artistic methods of carrying the mind back to the times before this Rip Van Winkle of architecture either went to sleep or was born. The result is indisputably charming. It is artistic archaeology tempered with civilization; the dish itself, as well as its trimmings, is Mediaeval; it does everything that is possible to put the hands of the clock back three or four centuries, but it is not modern architecture.

In ecclesiastical buildings we have similar results. The hapless chances of ancient church history and building are reproduced with skill and patience. The acme of modern ecclesiastical art consists in the perfect realization of what a beautiful fourteenth or fifteenth century church would have been, and as before, the laborious and earnest efforts of the artist had succeeded in a short span of life in running the gamut of the centuries and in reproducing in effect and feeling the presentment of the departed spirit of Mediaeval Art. In fact, often no higher praise is required than that the purity, beauty and other qualities of ancient Art are to be found in their present day counterfeit. We have a definite Renaissance of Mediaeval Art; our cathedral work. Our churches, large and small, and our colleges, are the productions of a living school of artistic architects for whom, with their domestic brethren, we cannot but feel the warmest affection and enthusiastic admiration, but they are exotics, they are contemporaries of Wykehamist William, of Harry the Eighth with his palace of Nonsuch, of Spencer and his Faerie Queen. They sing with Shakespeare:—

> Tell me where is fancy bred,
> Or in the heart, or in the head?
> How begot, how nourished?
> Reply, reply.
>
> It is engendered in the eyes,
> With gazing fed; and fancy dies
> In the cradle where it lies.
> Let us all ring fancy's knell;
> I'll begin it—Ding, dong, bell.

and they consistently suit the action to the word and bury true architectural fancy in a grave centuries deep.

We will not stop to discuss whether Queen Anne is dead or not, though she is evidently a guiding star still to the thirsty revivalist who, with faithful discrimination forsakes, with the progress of civilization, such barbarities as metal casements for the newly invented double-hung sash, and welcomes a small increase in the size of manufactured glass that enables him to employ wooden bars of moderate sect on instead of small lead straps. What would her deceased Majesty have given, or that great architect Sir Christopher Wren either, who preceded her, for such beautiful sheets of plate glass as now adorn our shop fronts? Oh, Revivalist, learn to follow the progressive movement of real Art, and become a designer in architecture instead of a mere dealer in her artistic antiquities. We must proceed to draw our conclusions. We are not able to complain of real lack of architectural opportunity, and there is no want of architectural genius and capacity. Our architects are, however, devoted to a more or less stupid archaeology, and therefore have ceased in any effective way to be artists for the age. Why should not this be remedied? Cannot we set ourselves, instead of against the stream of time and progress, with it? Why should not the requirements, methods and opportunities of the men of our own time be studied, and our minds trained to fix themselves upon the universal characteristics of living Art instead of upon its past impressions only? As there is no true Art in representing a laboring man, rough hewn and coarse perhaps, but perfectly beautiful in degree, at his rugged work, as wearing fine clothes or a mask of Apollo, so let a warehouse front represent a warehouse, a railway station appear to be what it is, and as a station only; and let this sensibleness and a simple beauty take the place of the hopeless affectations of domestic design, and we may yet begin to earn back again the wages of public esteem and confidence that we have forfeited by our archaeological heresies. Have you ever discovered that the true beauty of architecture is to do thoroughly and manifestly what it is intended to do, whether to be ornamental, comfortable, monumental or useful, as the case may require? For instance, what a solid impressiveness and grandeur there is about the vast supports and trabeated construction of the entrance of the Great Eastern Railway line into London, between Bethnal Green and Bishopsgate. This singular work of engineering is most architectural, and has stern and earnest beauty of character. Similar effects can be often, if not always, found where constructors have to make great effort to cope with difficulties, and some of the brick-and-girder engineering of the Metropolitan Railway is of this class, and has present in it, and manifestly so, most of the elements of sound architecture, and will without any doubt be regarded by the broad verdict of the future as some of the most characteristic buildings of our day. Why should architects segregate themselves, as if afflicted with an ancient leprosy, from the life of the city and world of to-day? Why should they leave all that is simple and direct in architecture to engineers, and lose their right to even the barren title of architect? Has not the Forth Bridge a piquant power of form and a real, if not ideal, beauty, without the assistance of what you and I call architecture? And does it not compare lamentably with the Tower Bridge, which, unless some undreamt-of convulsion happens, will for many generations be a monument of architectural failure, of great effort made to impart so-called Art and architecture that left to itself would have been much more natural? Also, in other directions, why are characteristic buildings of the age, such as the Crystal Palace and the Albert Hall, eminently works of architecture though not of architects? And, one must add, is not the block of Science Schools at Kensington, so impressive in mass and form and so thorough and beautiful in detail and decoration, the work of an architectural amateur, and does it not assert its dignity successfully amidst all its modern professional rivals?

Is it not time that we considered and reconsidered our methods until we find ourselves facing the problems of our practice, not as champions of a past style and dead art, but as equipped artists who facilitate the advance of architecture by meeting heartily the spirit of the age, in order to adapt her materials to their best uses, to accept her requirements for their greater usefulness, and to suitably and expressively ornament where required? To

discover the true beauty there is in all building truly and simply done, and to emphasize it, to proportion it, to mould it for the true enjoyment of all. To throw aside the trickeries of paper design, and to realize that such trifles as the small panes of glass of which we have spoken, with many others that are—foolish though it seems to say it—so indispensable to the modern architect, are quite unworthy of ourselves. Let us see that, shorn of a fictitious archæological interest, our buildings may be beautiful in themselves, as characteristic products of our high civilization. Be natural, as all the great architects have been before you. Learn by the true historical method the motive and spirit of past Art. See if the Greeks, who built a beautiful monument as a temple to Athene, together with the ecclesiastical and military engineers who erected the cathedrals and battlements of the Middle Ages, were not as far removed from you in the way they set about their work as possible. Was not their architecture the pure product of their age? and should not yours be so, too, in spite of that haunting fear of ugliness—indefinite enough for any bogey—which will cease to trouble you when once conscious that you have succeeded in doing simple and beautifully serviceable construction, adjusted and controlled by your trained artistic instinct?

The growth and practice of the great Renaissance of Art in the sixteenth century will bear the closest examination in the service of modern architecture. The motive of its artists is equally good, though widely different; but do not imagine that it was a mere revivalism of archæology. No restoration of ancient buildings was attempted; a genuine and wealthy architectural genius fed on the beauties of past ages, only to develop itself in the most wonderfully modern achievements, not only of construction and arrangement, but of detail and of all accessory art. Michel Angelo, in Rome, with the Baths of Caracalla and the Pantheon before him, conceived and constructed St. Peter's, and the true historical method of study that discerns how and with what ends he did it will take the idea and motive as its guide to like results. The study of the design, or rather designing, of any one great building at home or abroad is the most fruitful source of profit to the architectural student. The history of the idea of St. Peter's for instance, as it gradually grew from the work of Rosselina and Alberti to that of Bramante, San Gallo, Raphael and Peruzzi, before Angelo commenced his enormously grand and complete conception, is most inspiring and instructive, and of infinitely greater use than a complete calendar of every architect that ever was known, with dates and nicknames. This example of a great architect's power can be studied alongside with the expression of the same ideas of breadth and power of form in his sculptures and paintings, and in fact there is a whole education in the universality of artistic expression in such a historical study of principles. St. Paul's, London, is a similar example as we happily have the whole scheme from start to finish to study. Observe the way in which Wren grasped his problems, and grasp your own little ones with similar firmness, courage and breadth of idea. Take even more ancient buildings. Try St. Mark's, Venice, or an English cathedral and consider the alterations and additions, not as if executed in a delirium of irresponsible building fever, but as having a definite architectural purpose and idea in view. Why were these domes added? is a more important question than who added them. Why was this old front extended beyond all the limits of the buildings behind it? is a more important question than who did it, and did he know that it was a sham? Let us suggest to eminent examiners that the question, why is the Parthenon beautiful? is a much more vital one than in what technical terminology pedants would describe it, or how many columns compose the portico, and other like trivialities.

Until we seek to study the reason why things are beautiful, we shall never know how to design. Some naturally may have an intuitive perception that is denied to others, but for all that the beautiful is but the revelation of unseen truths, and when revealed by this perceptive faculty the lessons of the beautiful are manifest for all. The teachings of the ages are in the effects that their works produce upon our minds, and it is little short of absolute folly to confine the training of architects in design to exposition of the mere forms of the language of architecture and deny them insight into the meaning of the words used. Each stone, each plan embodies an idea that gave it existence at the hands of its constructor. Let us, as we have never done yet, seek to read this out of the stones, and enlarge our appreciation of beauty and the possibilities of the art of design accordingly.

FOREGIN ORNAMENTAL PLASTERING.

Although in England there may occasionally be seen some very handsome ornamental plaster work (principally executed during the last century by the Brothers Adam on the lines of Italian artists), it is not at home that we are to look for the higher examples of what may be done in ornamental plastering. Such work is mostly confined to ceiling spaces with us, and seldom found on walls, while, from India on the one hand to Peru on the other, we find it freely so used in other lands. It is, however, to Spain, whilst the Peninsula was under the rule of the Saracens, that we must look to see the grandest developments of what plaster is capable of. That fairy dream of architecture, the palace fortress of the Alhambra in Granada, built by the Moorish caliphs who ruled in that portion of Spain, has its ceilings and walls covered with decorative plaster work far excelling in beauty aught that Italian or Englishman ever dreamed of executing.

An American traveller, writing in the pages of a contemporary, speaks enthusastically of the "fanciful and light relievos which everywhere cover the wainscques Alhambra, and which, changing under the glance, like to the terns of a kaleidoscope, lend their peculiar power to charm fascinate the eye of the beholder. Like the little stories with each other in the tales of the 'Arabian Nights,' the figures are made up of repeated repetitions, so to speak, and yet, by their suggestive complexity, are ever new and never become wearisome. To the uninitiated the delicate intricacies of the arabesques covering the walls of the Alhambra appear to have been worked out by hand with minute and painstaking patience. Especially is this true of the domed ceilings, which, with their pendants and stalactites, present patterns of labyrinthine and bewildering complexity. When, however, it becomes apparent that all this is stucco work, our astonishment ceases, although our admiration for the design remains undiminished. The patterns are made in plates of plaster of paris, cast in moulds, and, being skilfully joined, form patterns of varied form and size.

"This style of diapering walls with arabesques, and stuccoing the vaults with grotto work, came originally from Damascus, but received its highest development and most pleasing imagery from the warm-blooded Moors of Spain.

"The process employed was simple. Preparatory to applying the decoration, the naked walls were divided by lines at right angles, such as artists employ in producing pictures. A series of intersecting segments of circles were then drawn over these, and by their aid the artist could work with quickness and surety. The great instrument of the Moorish artists was the compass, which, however, was not made in the usual way of two limbs of metal joined. It was a fixed measure, tied by a string, so that for each dimension there was a separate compass.

"Much of the glorious effect of the Saracenic decorations, however, depended on chromatic effect and these Moorish decorators were good colourists.

"Gilt was very freely applied on the stucco, especially on the vaults and cupolas. Brilliant and delicate colors, such as lapis-lazuli and vermillion, were used in the interstices, being applied with the white of egg. The primitive colours prevail in the Alhambra, wherever the artist has been Moorish or Arabian.

"The Hall of the Abencerrages is in the form of a perfect square, and the walls are ornamented with arabesques of the most elegant and intricate designs. The colors still retain their brilliancy, and the delicate beauty of the filagree remains unmarred after the lapse of more than 500 years.

"The Hall of the Two Sisters—so named by reason of two immense marble slabs forming part of its pavement is exceedingly beautiful. Stalactite roof is said to consist of 5,000, and though all this plaster ornamentation is supported only by reeds, it still remains well-nigh as perfect as when first placed there."

Turning now to quite another quarter of the globe, and one far distant from that of which we have just been speaking, let us glance at some extremely interesting specimens of ancient plaster work still to be found in Peru, in South America. As most people are aware, the Spanish Conquistadores, under Pizarro, Amalgeo, and others, found the natives of that country possessed of a civilization which mounted back to hoar antiquity. But Spain conquered and enslaved these Peruvians, and destroyed their temples and cities.

Quite recently (in 1862) Dr. Le Plongeon went to Peru, under the auspices of the California Academy of Sciences, to study the antiquities of the land, and he has explored a number of the ruins of early Peruvian houses and cities. His researches conclusively established the fact that these Indians were masters of concrete building and plastering. At Chimu Coucha he found the remains of some ancient ornamental stucco on the adobe (or clay-built) walls covered with bassi-relievi (low relief) decorative designs. Of course they are not equal to the marvellous Saracenic plaster at the Alhambra, of which we have spoken. Nevertheless, the designs are extremely good, and the material and the execution are both of high merit—in fact, it is impossible to restrain our wonder that a people ordinarily held to be but little better than savages could have conceived ornamentation so æsthetic and executed it with such high technical ability.

Space fails us to speak of work of a somewhat similar character executed by primitive races in India and elsewhere, while to treat of the production of Italian and other European craftsmen does not enter into our purview.

TREATMENT OF COLORS IN DIFFERENT LIGHTS*

A very essential feature, and a subject worthy of more study than is usually accorded it, is the treatment of light and shade in decorative art. I do not think there is a master painter who has not frequently been confronted by some very strange and inartistic ideas of his customers. In some cases by practical advice and illustration, these ideas may be modified and possibly result in a creditable job to customer and decorator. In the selection of wall hangings the goods are placed generally where a strong light prevails. This may be very well in some cases, but how often is it we hear that the paper looks better in the piece than on the wall! What is the reason? Is it the pattern? No! The customer has not considered the light in the room. The same defect may occur once in a while to the decorator. For example, a room may appear to be very light when devoid of curtains, shades, furniture, etc., and in this condition the work may indeed look very satisfactory when completed. But when the room is furnished, it lacks one thing—decision. What appeared to be a delicate ceiling, is now so delicate that it would take a pair of opera glasses to find the design.

There are men we sometimes run across, who think they know it all, but if there is any mechanic in the world of labor who has a broad field for study and food for reflection it is the house painter of to-day. It is the duty of the employer in the interest of himself and workmen to impress upon them the necessity of closer attention to the methods of decorative art. A few practical notes in reference to the treatment of colors in different lights, will, I think, not be out of place.

I call to your mind a room with a south or south-western exposure having at least two good-sized windows. Let the ceiling be treated with a groundwork of light cinnamon, frescoed in outline with a medium shade of old gold color, the high lights to be tipped with gold leaf. Let the side walls be grounded in a dull sage color as high as picture moulding. For frieze make a slightly darker shade and introduce ornament in colors of old gold, deep crimson and dull pink. The cornice should be treated with special care, and I suggest that the cove should have the main portion tinted in the body color of ceiling and blended down into gold at the completion of the arc. The members of the cornice above the cove should be in the lighter shades so that the whole may blend together towards the ceiling. Woodwork should be ivory white, rubbed to a dead finish. In furnishing this room I would suggest white and gold furniture, with upholstery of light amber tint or otherwise old rose. This would give contrast and harmony combined. Carpet should be of light fawn color, with just sufficient color in relief to show design. This would make a very desirable reception room or parlor.

We will take as another example, a room with a western outlook, a shady retreat as it were. Let the ceiling be of a medium shade of old rose color with stile about eighteen inches around it in peacock blue. Let ornamentation be in the main body of the ceiling, and consist of corners, breaks and lines of geometrical figures, to be in darker shade of body color, with strong lines of deep brown between centre and stile. Let the side walls be in a full and distinct shade of terra-cotta, leaving space for frieze about fourteen inches. Let two and one-half inches on top and bottom of frieze be tinted in free-stone color, the remaining nine inches in purple brown. Now take a double stencil of Grecian key border with eight inch figure, and use light free-stone color for same. As a relief make a panel or break, each three feet around room, the same height in full as frieze, that is, fourteen inches. Let this be a perfect square with a medallion in centre of each panel, introducing plaque pictures of the muses, literature, art and music. For colors let the outside of medallions be in the purple brown, and centres on which pictures are to be painted be pure gold-leaf. The outside edges of the panels may be treated as a mat, and I suggest their being beveled in light and shade. Treat the cornice with care. Let the cove be treated with the free-stone color, and upper members in terra cotta and old rose. Let the lower members be in purple and peacock blue. A great improvement to this room would be to stencil main members of cornice in imitation stucco work, using only colors as herein suggested. For a study, library or music room, I am sure this would gratify the taste of any lover of decorative art. Almost any kind of furniture will be in harmony here.

We will now go to the other side of the house, a room looking eastward. Let the ceiling be in two shades of pearl grey, very light, the darker shade to be placed on the outside edges of ceiling and extending towards center about twelve or fifteen inches, the two shades to be blended, not clouded into each other. Let the ornamentation be in garlands of flowers, twined naturally over a rustic branch. Let this take the shape of ceiling as closely as practicable and be about fourteen inches from cornice. The colors to be cheerful, but not overdone. Nature may be followed very closely on this background without going to extremes. Let side walls be tinted goblin blue, fairly light, with frieze in deeper shade. I would suggest as a pretty design for a frieze a festoon of roses tied at the commencement of each with a bow-knot. Let the cornice be tinted in the three shades of color, only upper members in color same as main body of ceiling. Cove in dark shade of same. Lower members to be in side wall tints, split only by one member in gold leaf. Going over this combination, in my mind, I can fancy how this room would look with a dining table tastefully laid with fruit and flowers interspersed with china and plate.

For a room with a northern outlook, here is a pretty and warm combination: Let the ceiling be painted in a rich cream color, devoid of ornamentation. If the walls are evenly laid out, coat them in a light salmon tint, have them struck out into panels according to the size of the room; let the ornament only form panel by running a chain pattern in border and corners in sage green and deep salmon. Outside this border run a pearl pattern in zinc white. Afterwards line off the whole with three-eighths inch vanish line about one and one-half inches from border. At the top of each panel paint a wreath of flowers tied with ribbon and hung gracefully in center. For frieze let the background be in a lighter shade of wall paper. In working this frieze select a stencil with full pattern, a festoon of various flowers with moderate sized leaves. Use thin, transparent colors for stenciling. After laying on each pattern wipe out high lights. Let the colors be as natural as possible, according to selection of flowers. Let the cornice be treated very lightly in color and allow two prominent members gold leaf on face. The woodwork may be in oak or ash, according to taste. This will make quite a handsome parlor or sitting-room.

I could say a great deal more on the subject, as there is always a sense of pleasure to the decorator while pursuing his interesting occupation. However, I conclude, trusting that my remarks may result in generous criticism, thereby educating us all through debate and practical attempts to improve.

*Paper read by W. T. Cochlan at the Third Annual Convention of the Society of Master House Painters and Decorators of New Jersey.

AUSTRALIAN WOOD PAVING BLOCKS FOR CANADA.

A letter has been received, says the Australasian Builder and Contractor's News, by Mr. Harry Wood, Under-Secretary for Mines and Agriculture, New South Wales, from Captain J. C. Rounding in reference to the offer of the Department in regard to wood blocks for Vancouver, B. C., Canada. Captain Rounding says he conveyed the offer of the Department to his friends in the City Council of Vancouver, and by last Saturday's mail he received a letter from their City Engineer, Mr. T. H. Tracey, as follows:—"I am directed by the City Council, in reply to your favor of the 17th March *re* wood blocks for paving, to say they will gladly accept your offer, and will have the blocks laid in the most substantial manner in a conspicuous place. The street selected is 264 feet by 50 feet between gutters, at the entrance to the C.P.R. station and wharfs, the rest of the street being laid or about to be laid with California bituminous rock on concrete foundations. I have copies of the best London specifications for block pavement, but would be pleased to receive particulars as to the mode of laying you have found best. Should you send more than one variety of wood blocks, I will see that they are laid so that they can be destinguished, and the qualities and life of each noted." Captain Rounding adds that the blocks will be laid in the most prominent and important part of the City of Vancouver, the main entrance to the Canadian-Pacific railway terminus station. The importance of the movement cannot be over estimated, and he has had inquries on the same subject from other parts of the Dominion. He thinks that if Australian wood blocks are once successfully adopted in Canada, the cities in the United States will soon follow suit.

PUBLICATIONS.

We have received from the publishers, the S. E. Hendricks Co., 61 Beekman street, New York, a copy of the 1894 issue of their Architects' and Builders' Guide and Contractors' Directory of America. The book has apparently been compiled and classified in a careful manner. Price $5.00.

Canadians will find the August number of the American Review of Reviews of more than ordinary interest. The articles by Mr. William B. Wallace on the Hon. Wilfrid Laurier, by Attorney-General Longley on "Canada's Political Condition," and by Dr. Albert Shaw on "Toronto as a Municipal Object Lesson," form the most important contribution to an understanding of Dominion interests and policies that has recently appeared in periodical literature.

There has just appeared from the press of Wm. T. Comstock, New York, a new Directory of the Architects of the United States and Canada. Architects who are members of any of the various architectural societies are indicated by figures placed after their names. While the publisher does not undertake to say that this directory is absolutely correct, he states that every effort has been made to ensure its accuracy. It is the publisher's intention to issue the Directory annually. The price has been fixed at the low figure of $1.00 per copy.

PERSONAL.

Mr. John Day, architect, of Guelph, who was confined to the hospital for some time as the result of an accident, is, we are pleased to learn, on the road to recovery.
